That's what Danny implied to his friends. Mason, a musician who wrote songs with Danny, is still under the impression that the discovery of the check was a scoop, a Danny Casolaro exclusive. But, as it turns out, the check had been made public by the congressional Iran-contra committee in 1987 and was well known to reporters in the field.

Ben Mason says that the real bombshell significance of the check is in its link to another document Danny showed him on the eve of his West Virginia trip: a passport photo of an Iraqi named Hassan Ibrahim, a reputed arms dealer. There are those who say that it was Ibrahim whom Danny was going to meet in West Virginia, that it was most likely Ibrahim who was the mysterious "Middle Eastern-looking man" Danny was seen with in the bar of the Sheraton Martinsburg the day before he died. But thus far nothing solid has turned up to suggest the whole magic "Missing Link check" act was anything other than a creative leap of speculation by Danny— if not a deliberate charade.

It should also be recalled that Danny was a novelist. And that he'd spoken to a number of his friends about possibly telling the whole Cabazon-Octopus story as a novel. His theatrical "I cracked the case" declarations in that final week suggest the thriller-novelist imagination at work, setting the stage for the obligatory mysterious murder essential to every spy thriller—in this case, his own.

The timing for all this is notable. The sudden flurry of melodramatic "I cracked the case" calls began at the end of July, shortly after Danny's nonfiction-Octopus-book proposal was rejected by the first mainstream publisher he sent it to, Little, Brown. One friend Danny called that final week remembers him "planting the seeds" earlier that summer. "Danny began telling me about these death threats he was getting on his answering machine, ' ' the friend says. ' ' And I said, 'Look, Danny, the telephone company can find ways to trace these calls.' And he got very embarrassed."

Meaning he faked it? I ask.

"Right." This friend's theory is that Danny knew he was suffering from some progressive debility, like M.S.— there'd been several "accidents" involving Danny's muscle coordination. That Danny knew he wouldn't or couldn't ever get his book written, in part because he wasn't sure what he really had. "What he did is throw a whole issue up against the wall so that it would be sorted out in some fashion." The friend believes that if Danny staged his death to look like murder, it would be "tragic," but also a "very wild, courageous," desperate attempt to get the truth out.

Then why leave a suicide note? Ann Klenk asked. It's a cogent objection. If he'd left no note, or, she suggests, if he'd driven his car off a cliff, or jumped off a building, then people would be more likely to speculate he'd been run off the road like Karen Silkwood, or he'd been pushed off the building he "jumped" from. She thinks if it was suicide it may well have been because "Danny finally found it all a crock," because the whole thing was "LaRouche sickthink, doublethink," and disinformation.

Some, however, cite the note itself as a clue to the murder. The note read, "To those who I love the most: Please forgive me for the worst possible thing I could have done. Most of all I'm sorry to my son. I know deep down inside that God will let me in."

Several of Danny's friends have told me emphatically that that last line— "God will let me in"—is the tip-off. That Danny, a Catholic, knew that suicides could not be "let in" to the Kingdom of Heaven. And that by including that line, by saying he would be "let in," he was signaling—under the noses, or under the guns, of his captors—that his death was not suicide.

Perhaps. But the best response to Ann Klenk's contention that he wouldn't have left a suicide note if he had wanted people to think he'd been murdered is, well. . .the actual reaction to his death. A VICTIM OF "THE OCTOPUS"? asked Newsweek in a full-page takeout. THE MAN WHO KNEW TOO MUCH? asked Time. CLOUDED IN MYSTERY,People said darkly two months after his death.

And that's only the mainstream media. Among the conspiracy theorists it's already an article of faith that Danny was assassinated. "A government-sanctioned hit," declares Virginia McCullough, a California-based October Surprise-conspiracy specialist who exchanged notes with Danny before he died. She says Danny was just the latest of several reporters murdered because of their October Stirprise investigations— all "government hits." Riconosciuto has added Danny's body to the fifty he says were murdered because of their proximity to him and his schemes. Danny's missing files have already begun to assume the all-purpose, prove-anything status of such other totems of conspiracy theory as the eighteen-minute gap on the Watergate tapes, the stolen papers of Howard Hughes, and the missing diary of Mary Meyer (the murdered J.F.K. mistress).

Several of Danny's friends have told me emphatically that the last line of his suicide note is the tip-off

And Danny himself—the reality of who he was and what he was really after— has begun to be subsumed by his enshrinement in the rolls of the martyrs to the great Octopoidal conspiracy in the sky.

That evening, in my room at the Sheraton Martinsburg, I climbed out of the bathtub. You stare too long at that cottage-cheese ceiling and you begin to see patterns coalescing in the pockmarked surface.

I sat down at the functional desk, trying to ignore the heavy-handed irony of the hotel's promotional card in front of me. It showed a picture of a knotted rope being stretched taut between two fists. This trip probably has you tied up in knots. . . . If you're at the end of your rope, give us a call. It was an ad for the hotel's massage service.

I tried to imagine Danny Casolaro at the end of his rope, stretched to the breaking point by his two sources, staring at that knotted cord.

For about the tenth time in the past twenty-four hours, I opened up Danny's last surviving notebook, one of those cheap composition notebooks with a speckled black-and-white cover. On the inside cover was a date: August 6, four days before Danny died. Wendy Weaver had just located it and supplied it to me, along with ten loose pages of notes which had not previously surfaced.

The notebook itself had only one page written on by Danny. There was only one substantive note:

Bill Hamilton Aug. 6

M.R. . . . also brought up Gilberto.

This is an apparent reference to the alleged Cali-coke-cartel kingpin who figured in the last murky Michael Riconosciuto quest Danny was pursuing

What caught my attention were the two names and phone numbers on that page, above the note, under the heading "To Call."

One name was "Jonathan," apparently Jonathan Beaty, the reporter who broke Time magazine's story on alleged B.C.C.I. hit squads.

The other was "Ron." Followed by my phone number.

He didn't call, but I suspect that if he'd reached me in the forty-eight hours before he left for Martinsburg he might well have told me some version of the "I finally cracked the case" riff. And I suppose if I'd heard it, it would have had the same effect on me: I would have been far more predisposed to believe the murder theory.

There is, of course, a legitimate, even compelling reason to pursue every piece of missing evidence, every discrepancy, every unexplained circumstance surrounding Danny's death—the reason Jack Anderson, dean of investigative columnists (who believes it's likely that Danny was murdered), gave: "Anytime a reporter is found dead while covering a story, it's a threat to all of us until the truth comes out." I don't think we should close the book on Danny Casolaro until we rule out the murder theory. Just as maybe a disturbing 5 percent of what Michael Riconosciuto says is credible, I'd say there's still a disturbing 5 percent chance that Danny Casolaro was murdered.

But I do have my own theory about what really killed Danny Casolaro. And the larger lesson his death has for us.

I believe that, in a sense, Danny was correct when he worried he might have been "targeted" with a "slow-acting brain virus." Not exactly the organic virus he worried about, not Mad Cow Disease or multiple sclerosis. Rather, I believe what destabilized Danny was an extremely virulent strain of the information virus we're suffering from collectively as a nation: Conspiracy Theory Fever. A slow-acting virus that has infected our ability to know the truth about the secret history of our age.

Don't get me wrong: I believe there are real conspiracies—Watergate was one; Iran-contra and C.I.A./Mafia plots against Castro were others. But those in the grip of Conspiracy Theory Fever seem compelled to believe that (to paraphrase the Flannery O'Connor title) everything that conspires must converge. That all conspiracies are tentacles of one big Octopoidal conspiracy that contains and explains everything.

The chief symptom of slow-acting brain viruses like Mad Cow Disease is that the brain becomes "spongiform," riddled with holes. The chief symptom of Conspiracy Theory Fever is that the brain becomes too sponge-like, too absorbent, indiscriminately accepting all facts and conjectures as equals, turning coincidence into causality, conjectures into certainties.

It's clear that toward the end Danny Casolaro fell victim to this kind of fever. He couldn't be content with the lowercase octopus of the Cabazon-reservation maze. He somehow had to convince himself and the rest of the world that he'd come upon the mega-conspiracy that explained everything. Even if he died trying.

Certainly a share of the blame for conspiracy fever must go to spooky sources like Riconosciuto and Clark Gable, to the LaRouchians, to paranoids-in-power like C.I.A. counterintelligence guru James Angleton, to the overly credulous Christie Institute types. And to the mainstream media, whose inadequate performance on the key scandal nexuses of our time have left the field open to the paranoids and opportunists who populate it with phantom Octopi.

Still, I think of Danny Casolaro not as a paranoid or opportunist but as a kind of Gatsbyesque conjurer, a feverish romantic illusionist.

The far-off glow Danny Casolaro yearned for was the illusory Ultimate Story, the one that would illuminate the source of the ongoing American nightmare. It was an illusion Danny loved so much he may well have given his life to make it seem true.

1990 (Oct 01) - Washington Post - "OBSESSED BY A THEORY OF CONSPIRACY"

Source - [HN01C5][GDrive]

By **S**and**ra Sugawara**

Sometimes in the still of the night, in the quiet of his living room or in the isolation of his car, Bill Hamilton will remember a forgotten conversation with a Justice Department official or a long ago phone call from a competitor or a colleague. And his mind will take that information, mull it over, turning it this way and that, as he tries to fit it into the puzzle that has become his life's obsession.

The puzzle: Why did a seemingly simple contract dispute over a software product evolve into a blood feud with the Justice Department, plunging his District computer software company, Inslaw Inc., into bankruptcy court for almost four years? And was somebody powerful trying to destroy his company?

"He's consumed by that one thought constantly," said his 19-year-old daughter Molly. "I'll see him in the living room and I can tell by the expression on his face that he's thinking about it. ... He's always working on it.".

The 49-year-old former National Security Agency analyst has spent much of his waking hours over the past several years trying to prove a conspiracy theory about his company's plight. Hamilton is convinced that Inslaw's primary product, a software system that enables the Justice Department to keep track of large numbers of legal cases, was the target of politically powerful people who sought to take it away from Inslaw and sell it themselves to the government.

Among his list of suspects are D. Lowell Jensen, a former top ranking Justice Department official, and Earl Brian, a member of Ronald Reagan's cabinet when he was governor of California and a friend of former attorney general Edwin Meese. All those on his list have denied any wrongdoing, in court documents and in interviews.

"To the best of my knowledge, I never met him and I have no knowledge of his operations," said Brian, who is chairman of United Press International and Infotechnology Inc. of New York. Brian said he believes that Hamilton is trying to recover money he has lost over the years "and any story he can come up with that is the least bitplausible hopefully will get him his day in court, from his perspective."

In the course of his battle, Hamilton has alienated some people, who claim that he is hostile to those who do not buy his theory. While acknowledging that Hamilton has a phenomenal memory for facts, they argue that he takes those facts and alters them to fit into his own agenda.

However, Hamilton also has marshaled an impressive list of supporters, including former attorney general Elliott Richardson and Charles R. Work, former president of the D.C. Bar, a lawyer's group. He also has gotten a number of sympathetic stories and editorials from a wide range of reporters and columnists who he regularly bombards with documents, memorandum and press releases.

Confounding opponents, skeptics and some considerable odds, Hamilton has won two crucial courtroom victories.

George F. Bason Jr., the bankruptcy judge who oversaw the Inslaw case, issued in 1987 a scathing condemnation of the Justice Department's behavior, declaring that the agency used "trickery, fraud and deceit" to steal Inslaw's computer software. Senior U.S. District Judge William B. Bryant of Washington backed up Bason's decision, awarding Hamilton $6.1 million in compensatory damages.

The Justice Department has appealed the case and will not discuss its details. A spokesman said that the department has requested that the matter be considered for mediation by the appeals court, in an attempt to settle the long-running dispute.

The decisions, however, did not establish the second half of Hamilton's theory, that Brian, Jensen and others were behind the alleged campaign against Inslaw. So last December Hamilton filed suit in U.S. District Court seeking to force Attorney General Richard Thornburgh and the Justice Department to conduct a "fair and thorough" investigation into his larger conspiracy charges. The latest suit will not bring him any money if he wins, just answers to his many questions.

A Justice Department spokesman said that the department already has looked into the accusations and found nothing. Hamilton argues that those investigations were inadequate. The Justice Department spokesman also noted that a Senate investigation failed to find evidence of a conspiracy against Inslaw within the Justice Department.

However, the Senate report also complained that the Justice Department was uncooperative in the investigation. Unhappy that the Senate probe was not more aggressive, Hamilton has convinced the House Judiciary Committee to launch one of its own. But the results of that investigation are expected to be several months away.

"A lot of people think Bill Hamilton is paranoid. I don't think so," said Leigh Ratiner, who represented Inslaw during the mid-1980s. "Bill Hamilton does not feel unreasonably persecuted. ... Given the facts, it's entirely reasonable to feel the way he does."

Ratiner explained Hamilton this way: "Bill is besieged by the need to find justice and vindicate his life, his management capabilities and look good in the eyes of his family and employees."

But Hamilton said the root of his obsession is justice, not personal vindication. His company will not get a fair break from the government until his enemies are exposed, he said.

"The thing that's important to understand," said Hamilton, "is not only are we determined to get a fair and thorough and independent investigation of this matter, but we have no choice."

When Hamilton says this, he does not pound his fist or shout. His indictment proceeds as a matter-of-fact litany of names, dates, places and conversations, as he peers intently at the listener from behind his wire-rimmed glasses, as if to ask: "Do you get it?"

Or sometimes, after he presents a laundry list of wrongs he believes were committed against Inslaw, a sad but youthful grin will break out from behind his graying beard and he'll quietly shake his head in disbelief.

Software Called Promis Hamilton's pride and joy is a pioneering computer software called Promis (Prosecutors Management Information System), which was designed to help prosecutors and lawyers keep track of their cases.

Initially, Promis was developed with federal funds from the now-defunct Law Enforcement Assistant Administration (LEAA), when Inslaw was the nonprofit Institute for Law and Social Research. But in the late 1970s, when it became obvious that LEAA would be phased out, Hamilton decided to turn Inslaw into a for-profit company and sell the software improvements to the government.

Hamilton, a Notre Dame University graduate and St. Louis native, said he was just a naive Midwesterner back in those days, but even then, he appreciated the value of connections. He hired Roderick Hills, former chairman of the Securities and Exchange Commission, as one of his lawyers. A fortuitous choice,

Hills introduced Hamilton to an attorney who would come to play a key role in Inslaw's fate: Elliot L. Richardson.

Richardson originally was brought in to serve on a board of directors, but as Inslaw became more and more entangled in its feud with the Justice Department, it was Richardson who would serve as troubleshooter. Richardson's frequent calls, sometimes from airports or late at night, often boosted Hamilton's morale. And it was Richardson who gave Inslaw's case legitimacy in Congress and elsewhere, according to many.

"The more I got into this case, the angrier I got," at what was happening to Inslaw, Richardson said. "It goes to the heart of the integrity of the Department of Justice itself." He added, "In any situation where there is this much evidence ... to just brush aside this evidence is destructive of public confidence."

In retrospect, Hamilton said there were warning signs almost as soon as Inslaw won the three-year, $10 million contract from the Justice Department in March 1982 to install Promis software in the offices of U.S. attorneys across the country. Almost immediately, attorneys for Inslaw and the Justice Department were fighting over which improvements the government had financed and thus owned, and which enhancements belonged to Inslaw.

Hamilton said the dispute became unusually contentious.

Back then, Hamilton thought his problems could be directly traced to the project manager overseeing the Promis contract, C. Madison Brewer III. From 1974 to 1976, Brewer worked for Inslaw. Hamilton said he fired Brewer; the government said he resigned. Brewer declined to comment on the Inslaw case.

Hamilton said he tried to avoid Brewer, letting other company officials negotiate with him, believing that might make things go more smoothly. But by February 1985, the Justice Department had withheld $1.2 million in payments to Inslaw, forcing the company to file a Chapter 11 bankruptcy petition, staving off creditors while it attempted to regain control of its finances.

The entire family quickly became drawn into the survival fight.

"Bill and I are down here {at the office} from morning until late at night, and our kids are calling, saying that the sheriff was at the door looking to serve subpoenas to us," said a still angry Nancy Hamilton, Bill's wife, who joined the firm in late 1984 as vice president of administration. "It was very frightening for the kids."

After Richardson tried unsuccessfully for nearly a year to settle the dispute, the Hamiltons decided in 1986 to take the offensive, suing the Justice Department to recover the money they said they had lost.

Competing Program

Hamilton was forever digging through his old appointment books, memos and scribbled notes. One night, he said, he was jolted awake by the recollection of a forgotten conversation: A Justice Department official had confidentially told one of his attorneys that Brewer was not his only problem. At the time, Hamilton had assumed this was a reference to D. Lowell Jensen, a senior Justice Department official.

Before coming to the Justice Department, Jensen had been in the Alameda County, Calif., prosecutor's office, where he had supervised the development of a competing case-tracking software called Dalite. Jensen was disappointed when the Los Angeles district attorney's office and LEAA had opted for Promis, according to Hamilton. He now believes Jensen was part of the Justice Department group that allegedly wanted to get Inslaw.

Jensen, who is now a federal judge in San Francisco, declined to comment, through an assistant.

Seeing Shadows Everywhere

Before long, the Hamiltons acknowledge, they were seeing shadows everywhere.

"By this time, we were really distrusting," said Nancy Hamilton. The Hamiltons even became suspicious of the motives of the law firm they had hired, Dickstein Shapiro & Morin.

Hamilton began hearing from Ratiner, who was the Dickstein Shapiro attorney handling the case, that others in the firm felt Inslaw should stick to the narrow facts of the contract dispute and not go after Jensen.

The Hamiltons concluded that the Justice Department was pressuring the law firm to drop Jensen from the suit and that Dickstein Shapiro was selling out Inslaw to protect its ties with its more politically important clients. The law firm categorically denied Hamilton's assertions during a later court battle with Inslaw over legal fees and a Baltimore bankruptcy judge later ruled in favor of Dickstein Shapiro, clearing it of all malpractice accusations.

But it was these fears that caused the Hamiltons to take a most unusual step. They decided to file the suit themselves, before Dickstein Shapiro could make any changes in the legal papers.

On June 7, 1986, the Hamiltons told Ratiner of their plans. He urged them to wait. "Normally it's easy for a lawyer to intimidate a client," Ratiner said. "But not Bill."

Joined by their six children, ages 3 to 22, the Hamiltons piled into their 1963 Volkswagen and their Oldsmobile station wagon and headed down to the U.S. District Court for the District of Columbia. To photograph the event, they brought along a girlfriend of their oldest daughter Patty.

"It was a big day in our lives because for the first time, we understood what was happening to us and we had an opportunity to protest, it was quite a milestone," said Nancy Hamilton. "It makes me emotional to talk about it even now."

In October, Ratiner called to say he was being fired from Dickstein Shapiro. The Hamiltons said they were convinced it was because of the Inslaw case. Ratiner, who now teaches international negotiations at American University and has a small company specializing in data entry services, declined to comment on the question.

Work, a longtime friend of Hamilton's, was able to work out a temporary truce but Dickstein Shapiro and Hamilton parted for good when the firm concluded that Hamilton had overstated the improvements to the software produced by Inslaw. "

Thus in 1987, Inslaw was preparing to go to trial against the government without a lawyer and in the middle of a bankruptcy reorganization.

A determined Hamilton convinced two lawyer friends in California to fly to Washington and help out with the deposition. For a week, the two lawyers slept in one of the children's rooms in the Hamilton's house and took depositions from morning until night.

When Hamilton's lawyer friends returned to California, he prevailed on Work to take his case.

Work and Hamilton had worked closely together in the early 1970s when Work was an assistant U.S. Attorney, supervising the installation of the LEAA-funded versions of the Promis software. Work also served as deputy administrator of LEAA under Richardson.

Favorable Ruling The ruling by bankruptcy judge Bason in September 1987 elated the Hamiltons.

Bason concluded that Brewer was biased against Inslaw and that the Justice Department's "failure to begin to investigate Inslaw's complaints was outrageous and indefensible. It constituted an institutional decision by the Department of Justice, consciously made at the highest level, simply to ignore serious questions of ethical impropriety ... "

Although the ruling was critical of Jensen, too, it did not spell out the conspiracy that Hamilton said he believes existed.

The celebration over the ruling had barely ended before Hamilton was back on the case, his suspicions inflamed anew. A journalist who knew about Hamilton's fight mentioned to him that the Justice Department had awarded a computer contract to a subsidiary of Hadron Inc., a Fairfax government contracting company.

The reporter explained that Brian owned a major share of Hadron. The reporter also reminded him that the Meeses' had invested in one of Brian's companies. Suddenly, the name Hadron rang a bell. He hung up the telephone, turned to his wife and said: " 'Hadron! I think that company called me to try to buy me in '83.' I went to my desk calender, one of the old ones, started going through those months until I found it: April 20, 1983, with the name Dominic Laiti and his telephone number."

Hamilton remembers the phone call this way: Laiti, then chairman of Hadron, told Hamilton he was interested in the Promis software and wanted to buy Inslaw to get it. Hamilton replied that the company wasn't for sale.

Hamilton quotes Laiti as replying: "We have political supporters at the highest level of the Reagan administration," and "We have ways of making you sell."

Laiti, who is now president of Globalink Language Service, said he never tried to buy Inslaw, nor does he remember ever talking to Hamilton.

Assistance From IBM Bason's ruling pulled Inslaw out of the ditch. On Dec. 31, 1988, the company emerged from bankruptcy with the assistance of International Business Machines Corp. The computer giant had long been interested in jointly marketing Promis software and loaned the company $2.5 million.

Almost a year later, the Hamiltons got more good news.

On Nov. 22, 1989, the Court of Appeals confirmed the bankruptcy court decision against the Justice Department.

The appeals court said "Inslaw performed its contract in a hostile environment that extended from the higher echelons of the Justice Department to the officials who had the day-to-day responsibility for supervising its work."

The court concluded that the government "acted willfully and fraudulently to obtain property that it was not entitled to under the contract."

Tracking Down Leads Inslaw is still at the 15th Street offices where it has been since 1974. The office is filled with sleek furniture, dressed-for-success employees and other trappings of a successful computer software company. It has developed new sales with state and local governments and law firms.

But Hamilton still spends a good part of each week trying to track down leads on the case. He rarely watches television and hates sports. Occasionally he rents videos. One of his favorite movies in recent times was "All the President's Men," about the Watergate conspiracy.

Hamilton also has become a repository of phone calls from people who feel wronged by the government. He said he listens to them all, no matter how far out, because he understands their frustrations and is more that willing to believe the abuses they describe.

Today, suspicion of the government runs in his marrow. Was he like this before? No, Hamilton said.

"It might be that nobody will know who the real Bill Hamilton is again," said Ratiner. "For instance, I can imagine that before this case, he might have been concerned about real people. But now, if you're not talking to him about Inslaw, you're kind of invisible."

Hamilton said he's sad about the times he could not be there for friends, for family and about the part of his life that has been robbed by this case.

"I'm angry," Hamilton finally said quietly, after first skirting around the issue of his feelings. "I have enough anger to last me for a generation."

1993 (Jan) Wired Magazine - "The INSLAW Octopus : SOFTWARE PIRACY, CONSPIRACY, cover-up, stonewalling, covert action: Just another decade at the Department of Justice"

Source : [HP004F][GDrive]

The House Judiciary Committee lists these crimes as among the possible violations perpetrated by "high-level Justice officials and private individuals":

- Conspiracy to commit an offense
- Fraud
- Wire fraud
- Obstruction of proceedings before departments, agencies and committees
- Tampering with a witness

- Tampering with a witness
- Retaliation against a witness
- Perjury
- Interference with commerce by threats or violence
- Racketeer Influenced and Corrupt Organizations (RICO) violations
- Transportation of stolen goods, securities, moneys
- Receiving stolen goods

Bill Hamilton, Inslaw & PROMIS

Who:

Bill Hamilton and his wife, Nancy Hamilton, start Inslaw to nurture PROMIS (Prosecutors Management Information Systems).

Why #1:

The DOJ, aware that its case management system is in dire need of automation, funds Inslaw and PROMIS. After creating a public-domain version, Inslaw makes significant enhancements to PROMIS and, aware that the US market for legal automation is worth $3 billion, goes private in the early '80s.

Why #2:

Designed as case-management software for federal prosecutors, PROMIS has the ability to combine disparate databases, and to track people by their involvement with the legal system. Hamilton and others now claim that the DOJ has modified PROMIS to monitor intelligence operations, agents and targets, instead of legal cases.

By late November, 1992 the nation had turned its attention from the election-weary capital to Little Rock, Ark., where a new generation of leaders conferred about the future. But in a small Washington D.C. office, Bill Hamilton, president and founder of Inslaw Inc., and Dean Merrill, a former Inslaw vice president, were still very much concerned about the past.

The two men studied six photographs laid out before them. "Have you ever seen any of these men?" Merrill was asked. Immediately he singled out the second photo. In a separate line up, Hamilton's secretary singled out the same photo.

Both said the man had visited Inslaw in February 1983 for a presentation of PROMIS, Inslaw's bread-and-butter legal software. Hamilton, who knew the purpose of the line-up, identified the visitor as Dr. Ben Orr. At the time of his visit, Orr claimed to be a public prosecutor from Israel.

Orr was impressed with the power of PROMIS (Prosecutors Management Information Systems), which had recently been updated by Inslaw to run on powerful 32-bit VAX computers from Digital Equipment Corp. "He fell in love with the VAX version," Hamilton recalled.

Dr. Orr never came back, and he never bought anything. No one knew why at the time. But for Hamilton, who has fought the Department of Justice (DOJ) for almost 10 years in an effort to salvage his business, once his co- workers recognized the man in the second photo, it all made perfect sense.

For the second photo was not of the mysterious Dr. Orr, it was of Rafael Etian, chief of the Israeli defense force's anti-terrorism intelligence unit. The Department of Justice sent him over for a look at the property they were about to "misappropriate," and Etian liked what he saw. Department of Justice documents record that one Dr. Ben Orr left the DOJ on May 6, 1983, with a computer tape containing PROMIS tucked under his arm.

What for the past decade has been known as the Inslaw affair began to unravel in the final, shredder-happy days of the Bush administration. According to Federal court documents, PROMIS was stolen from Inslaw by the Department of Justice directly after Etian's 1983 visit to Inslaw (a later congressional investigation preferred to use the word "misappropriated"). And according to sworn affidavits, PROMIS was then given or sold at a profit to Israel and as many as 80 other countries by Dr. Earl W. Brian, a man with close personal and business ties to then-President Ronald Reagan and then-Presidential counsel Edwin Meese.

A House Judiciary Committee report released last September found evidence raising "serious concerns" that high officials at the Department of Justice executed a pre-meditated plan to destroy Inslaw and co-opt the rights to its PROMIS software. The committee's call for an independent counsel have fallen on deaf ears. One journalist, Danny Casolaro, died as he attempted to tell the story (see sidebar), and boxes of documents relating to the case have been destroyed, stolen, or conveniently "lost" by the Department of Justice.

But so far, not a single person has been held accountable.

WIRED has spent two years searching for the answers to the questions Inslaw poses: Why would Justice steal PROMIS? Did it then cover up the theft? Did it let associates of government officials sell PROMIS to foreign governments, which then used the software to track political dissidents instead of legal cases? (Israel has reportedly used PROMIS to track troublesome Palestinians.)

The implications continue: that Meese profited from the sales of the stolen property. That Brian, Meese's business associate, may have been involved in the October Surprise (the oft-debunked but persistent theory that the Reagan campaign conspired to insure that US hostages in Iran were held until after Reagan won the 1980 election, see sidebar). That some of the moneys derived from the illegal sales of PROMIS furthered covert and illegal government programs in Nicaragua. That Oliver used PROMIS as a population tracking instrument for his White House-based domestic emergency management program.

Each new set of allegations leads to a new set of possibilities, which makes the story still more difficult to comprehend. But one truth is obvious: What the Inslaw case presents, in its broadest possible implications, is a painfully clear snapshot of how the Justice Department operated during the Reagan-Bush years.

This is the case that won't go away, the case that shows how justice and public service gave way to profit and political expediency, how those within the administration's circle of privilege were allowed to violate private property and civil rights for their own profit.

Sound like a conspiracy theorist's dream? Absolutely. But the fact is, it's true.

The Background

Imagine you are in charge of the legal arm of the most powerful government on the face of the globe, but your internal information systems are mired in the archaic technology of the 1960s. There's a Department of Justice database, a CIA database, an Attorney's General database, an IRS database, and so on, but none of them can share information. That makes tracking multiple offenders pretty darn difficult, and building cases against them a long and bureaucratic task.

Along comes a computer program that can integrate all these databases, and it turns out its development was originally funded by the government under a Law Enforcement Assistance Administration grant in the 1970s. That means the software is public domain ... free!

Edwin Meese was apparently quite taken with PROMIS. He told an April 1981 gathering of prosecutors that PROMIS was "one of the greatest opportunities for [law enforcement] success in the future." In March 1982, Inslaw won a $9.6 million contract from the Justice Department to install the public domain version of PROMIS in 20 US Attorney's offices as a pilot program. If successful, the company would install PROMIS in the remaining 74 federal prosecutors' offices around the country. The eventual market for complete automation of the Federal court system was staggering: as much as $3 billion, according to Bill Hamilton. But Hamilton would never see another federal contract.

Designed as a case-management system for prosecutors, PROMIS has the ability to track people. "Every use of PROMIS in the court system is tracking people," said Inslaw President Hamilton. "You can rotate the file by case, defendant, arresting officer, judge, defense lawyer, and it's tracking all the names of all the people in all the cases."

What this means is that PROMIS can provide a complete rundown of all federal cases in which a lawyer has been involved, or all the cases in which a lawyer has represented defendant A, or all the cases in which a lawyer has represented white-collar criminals, at which stage in each of the cases the lawyer agreed to a plea bargain, and so on. Based on this information, PROMIS can help a prosecutor determine when a plea will be taken in a particular type of case.

But the real power of PROMIS, according to Hamilton, is that with a staggering 570,000 lines of computer code, PROMIS can integrate innumerable databases without requiring any reprogramming. In essence, PROMIS can turn blind data into information. And anyone in government will tell you that information, when wielded with finesse, begets power. Converted to use by intelligence agencies, as has been alleged in interviews by ex-CIA and Israeli Mossad agents, PROMIS can be a powerful tracking device capable of monitoring intelligence operations, agents and targets, instead of legal cases.

At the time of its inception, PROMIS was the most powerful program of its type. But a similar program, DALITE, was developed under another LEAA grant by D. Lowell Jensen, the Alameda County (Calif.) District Attorney. In the mid-1970s, the two programs vied for a lucrative Los Angeles County contract and Inslaw won out. (Early in his career, Ed Meese worked under Jensen at the Alameda County District Attorney's office. Jensen was later appointed to Meese's Justice Department during the Reagan presidency.)

In the final days of the Carter administration, the LEAA was phased out. Inslaw had made a name for itself and Hamilton wanted to stay in business, so he converted Inslaw to a for-profit, private business. The new Inslaw did not own the public domain version of PROMIS because it had been developed with LEAA funds. But because it had funded a major upgrade with its own money, Inslaw did claim ownership of the enhanced PROMIS.

Through his lawyers, Hamilton sent the Department of Justice a letter outlining his company's decision to go private with the enhanced PROMIS. The letter specifically asked the DOJ to waive any proprietary rights it might claim to the enhanced version. In a reply dated August 11, 1982, a DOJ lawyer wrote: "To the extent that any other enhancements (beyond the public domain PROMIS) were privately funded by Inslaw and not specified to be delivered to the Department of Justice under any contract or other agreement, Inslaw may assert whatever proprietary rights it may have."

Arnold Burns, then a deputy attorney general, clarified the DOJ's position in a now-critical 1988 deposition: "Our lawyers were satisfied that Inslaw's lawyers could sustain the claim in court, that we had waived those [proprietary] rights."

The enhancements Inslaw claimed were significant. In the 1970s the public- domain PROMIS was adapted to run on Burroughs, Prime, Wang and IBM machines, all of which used less-powerful 16-bit architectures. With private funds, Inslaw converted that version of PROMIS to a 32-bit architecture running on a DEC VAX minicomputer. It was this version that Etian saw in 1983. It was this version that the DOJ stole later that year through a pre-meditated plan, according to two court decisions.

The Dispute Grows

On a gorgeous spring morning in 1981, Lawrence McWhorter, director of the Executive Office for US Attorneys, put his feet on his desk, lit an Italian cigar, eyed his subordinate Frank Mallgrave and said through a haze of blue smoke: "We're out to get Inslaw."

McWhorter had just asked Mallgrave to oversee the pilot installation of PROMIS, a job Mallgrave refused, unaware at the time that he was being asked to participate in Inslaw's deliberate destruction.

"We were just in his office for what I call a B.S. type discussion," Mallgrave told WIRED. "I remember it was a bright sunny morning.... (McWhorter) asked me if I would be interested in assuming the position of Assistant Director for Data Processing...basically working with Inslaw. I told him...I just had no interest in that job. And then, almost as an afterthought, he said 'We're out to get Inslaw.' I remember it to this day."

After Mallgrave refused the job, McWhorter gave it to C. Madison "Brick" Brewer. Brewer at one time worked for Inslaw, but was allowed to resign when Hamilton found his performance inadequate, according to court documents. Brewer was then hired into the Department of Justice specifically to oversee the contract of his former employer. (The DOJ's Office of Professional Responsibility ruled there was no conflict of interest.) He would later tell a federal court that everything he did regarding Inslaw was approved by Deputy Attorney General Lowell Jensen, the same man who once supervised DALITE, the product which lost a major contract to Inslaw in the 1970s.

Brewer, who now refuses to comment on the Inslaw case, was aided in his new DOJ job by Peter Videnieks. Videnieks was fresh from the Customs Service, where he oversaw contracts between that agency and Hadron, Inc., a company controlled by Meese and Reagan-crony Earl Brian. Hadron, a closely held government systems consulting firm, was to figure prominently in the forthcoming scandal.

According to congressional and court documents, Brewer and Videnieks didn't tarry in their efforts to destroy Inslaw. After Inslaw's installation of public domain PROMIS had begun, the DOJ claimed that Inslaw, which was supporting the installation with its own computers running the enhanced version of PROMIS, was on the brink of bankruptcy. Although Inslaw was contracted to provide only the public domain PROMIS, the DOJ demanded that Inslaw turn over the enhanced version of PROMIS in case the company could not complete its contractual obligations. Inslaw agreed to this contract modification, but on two conditions: that the DOJ recognize Inslaw's proprietary rights to enhanced PROMIS, and that the DOJ not distribute enhanced PROMIS beyond the boundaries of the contract (the 94 US Attorney's offices.)

The DOJ agreed to these conditions, but requested Inslaw prove it had indeed created enhanced PROMIS with private funds. Inslaw said it would, and the enhanced software was given to the DOJ.

Once the DOJ had control of PROMIS, it dogmatically refused to verify that Inslaw had created the enhancements, essentially rendering the contract modification useless. When Inslaw protested, the DOJ began to withhold payments. Two years later, Inslaw was forced into bankruptcy.

As the contract problems with DOJ emerged, Hamilton received a phone call from Dominic Laiti, chief executive of Hadron. Laiti wanted to buy Inslaw. Hamilton refused to sell. According to Hamilton's statements in court documents, Laiti then warned him that Hadron had friends in the government and if Inslaw didn't sell willingly, it would be forced to sell.

Those government connections included Peter Videnieks over at the Justice Department, according to John Schoolmeester, Videnieks' former Customs Service supervisor. Laiti and Videnieks both deny ever meeting or having any contact, but Schoolmeester has told both WIRED and the House Judiciary Committee it was "impossible" for the pair not to know each other because of the type of work and oversight involved in Hadron's relationship with the Customs Service. Schoolmeester also said that because of Brian's relationship with then-President Reagan (see sidebar), Hadron was considered an "inside" company.

The full-court press continued. In 1985 Allen & Co., a New York investment banking concern with close business ties to Earl Brian, helped finance a second company, SCT, which also attempted to purchase Inslaw. That attempt also failed, but in the process a number of Inslaw's customers were warned by SCT that Inslaw would soon go bankrupt and would not survive reorganization, Hamilton said in court documents.

Broke and with no friends in the government, on June 9, 1986, Inslaw filed a $30 million lawsuit against the DOJ in bankruptcy court. Inslaw's attorney for the case (he was later fired from his firm under extremely suspicious circumstances – see sidebar) was Leigh Ratiner of the Wash- ington firm Dickstein, Shapiro & Morin. Ratiner chose bankruptcy court for the filing based on the premise that Justice, the creditor, had control of PROMIS. He explained recently, "It was forbidden by the BankruptcyAct for the creditor to exercise control over the debtor property. And that theory – that the Justice Department was exercising control – was the basis that the bankruptcy court had jurisdiction.

"As far as I know, this was the first time this theory had been used," Ratiner told WIRED. "This was ground-breaking. It was, in fact, a legitimate use of the code."

It worked, but to only a point. In 1987, Washington, D.C., bankruptcy judge George Bason ruled in a scathing opinion that Justice had stolen PROMIS through "trickery, fraud and deceit." He awarded Inslaw $6.8 million in damages and, in the process, found that Justice Department officials made a concerted effort to bankrupt Inslaw and place the company's enhanced PROMIS up for public auction (where it would then be fodder for Brian's Hadron). Bason's findings of fact relied on testimony from Justice employees and internal memoranda, some of which outlined a plan to "get" PROMIS software.

Bason cited the testimony of a number of the government's defense witnesses as being "unbelievable" and openly questioned the credibility of others. In his 216-page ruling, Bason cites numerous instances where testimony from government witnesses is contradictory. (In a private interview with WIRED he noted that as a bankruptcy judge he was precluded from bringing perjury charges against government employees, but he had recommended to various congressional panels that an inquiry was necessary.)

When the DOJ appealed, a federal district court affirmed Bason, ruling that there was "convincing, perhaps compelling support for the findings set forth by the bankruptcy court." But the D.C. Circuit Court of Appeals reversed the case on a legal technicality, finding that the bankruptcy court had no jurisdiction to hear the damages claim. A petition to the Supreme Court in October 1991 was denied review.

The IRS got into the act as well. Inslaw was audited several times in the course of their battles with the Department of Justice. In fact, the day following the bankruptcy trial, S. Martin Teel, a lawyer for the IRS, requested that Judge Bason liquidate Inslaw. Bason ruled against Teel. As a coda to the lawsuit, Bason, a respected jurist, was not re-appointed to the bench when his term expired. His replacement? S. Martin Teel. (Bason has testified before Congress that the DOJ orchestrated his replacement as punishment for his rulings in the Inslaw case.)

But Inslaw's troubles did not end with bankruptcy. Frustrated by Attorney General Dick Thornburgh's stubborn refusal to investigate the DOJ or appoint an independent prosecutor, Elliot Richardson, President Nixon's former attorney general and a counsel to Inslaw for nearly 10 years (he retired this January), filed a case in U.S. District Court demanding that Thornburgh investigate the Inslaw affair. In 1990, the court ruled that a prosecutor's decision not to investigate – "no matter how indefensible" – cannot be corrected by any court. Another loss for Inslaw.

Broke and still attempting to revive itself, Inslaw has not refiled its suit, preferring to wait for a new administration and a new DOJ.

By this time, the spinning jennies of the conspiracy network had grasped the Inslaw story and were all-too-eager to put their stitch in the unraveling yarn. According to documents and affidavits filed during court cases and congressional inquiries, the Hamiltons and their lawyers began receiving phone calls, visits and memos from a string of shadowy sources, many of them connected to international drug, spy and arms networks. Their allegations: That Earl Brian helped orchestrate the October Surprise for then-candidate Reagan, and that Brian's eventual payment for that orchestration was a cut of the PROMIS action. Brian and the DOJ then resold or gave PROMIS to as many as 80 foreign and domestic agencies. (Brian adamantly denies any connection to Inslaw or the October Surprise.)

These sources, which include ex-Israeli spy Ari Ben Menashe and a computer programmer of dubious reputation, Michael Riconosciuto, allege that PROMIS had been further modified by the DOJ so that any agency using it could be subject to undetected DOJ eavesdropping – a sort of software Trojan Horse. If these allegations are true, by the late 1980s PROMIS could have become the digital ears of the US Government's spy effort – both internal and external. Certainly something the administration wouldn't want nosy congressional committees looking into.

The diaphanous web of more than 30 sources who offered information to Inslaw were not "what a lawyer might consider ideal witnesses," Richardson admitted. But their stories yielded a surprising consistency. "The picture that emerges from the individual statements is remarkably detailed and consistent," he wrote in an Oct. 21, 1991 New York Times Op Ed.

The Congressional Investigation

The string of lawsuits and widening allegations caught the eye of House Judiciary Committee Chairman Jack Brooks, D-Texas, who in 1989 launched a three-year investigation into the Inslaw affair. In the resulting report, the Committee suggested that among others, Edwin Meese, while presidential counselor and later as attorney general, and D. Lowell Jensen, a former assistant and deputy attorney general and now a US district judge in San Francisco, conspired to steal PROMIS.

"High government officials were involved," the report states. "... (S)everal individuals testified under oath that Inslaw's PROMIS software was stolen and distributed internationally in order to provide financial gain and to further intelligence and foreign policy objectives."

"Actions against Inslaw were implemented through the Project Manager (Brick Brewer) from the beginning of the contract and under the direction of high-level Justice Department officials," the report says. "The evidence...demonstrates that high-level Department officials deliberately ignored Inslaw proprietary rights and misappropriated its PROMIS software for use at locations not covered under contract with the company."

The Committee report accuses former Attorney General Dick Thornburgh of stonewalling congressional inquiries, turning a blind eye to the possible destruction of evidence within the Justice Department, and ignoring the DOJ's harassment of employees questioned by Congressional investigators.

Rep. Brooks told WIRED that the report should be the starting point for a grand jury investigation. The owners of Inslaw, Brooks said, were "ravaged by the Justice Department...treated like dogs."

Brooks' committee voted along party lines, 21-13, to adopt the investigative report on Aug. 11, 1992. The report asked then-Attorney General William Barr to "immediately settle Inslaw's claims in a fair and equitable manner" and "strongly recommends that the Department seek the appointment of an Independent Counsel."

As he did with the burgeoning Iraqgate scandal and as his predecessor did before him, Barr refused to appoint an independent counsel to the Inslaw case, relying instead on a retired federal judge, in this case Nicholas Bua, who reported to Barr alone. In other words, the DOJ was responsible for investigating itself.

"The way in which the Department of Justice has treated this case, to me, is inexplicable," Richardson told WIRED. "I think the circumstances most strongly suggest that there must be wider ramifications."

The Threads Unravel

Proof of those wider ramifications are just starting to leak out, as DOJ and other agency employees begin to talk, although for the most part they spoke to WIRED only on condition of anonymity.

On Nov. 20, 1990, the Judiciary Committee wrote a letter asking CIA director William Webster to help the committee "by determining whether the CIA has the PROMIS software."

The official reply on December 11th: "We have checked with Agency components that track data processing procurement or that would be likely users of PROMIS, and we have been unable to find any indication that the Agency ever obtained PROMIS software."

But a retired CIA official whose job it was to investigate the Inslaw allegations internally told WIRED that the DOJ gave PROMIS to the CIA. "Well," the retired official told WIRED, "the congressional committees were after us to look into allegations that somehow the agency had been culpable of what would have been, in essence, taking advantage of, like stealing, the technology [PROMIS]. We looked into it and there was enough to it, the agency had been involved."

How was the CIA involved? According to the same source, who requested anonymity, the agency accepted stolen goods, not aware that a major scandal was brewing. In other words, the DOJ robbed the bank, and the CIA took a share of the plunder.

But the CIA was not the only place where illegal versions of PROMIS cropped up. Canadian documents (held by the House Judiciary Committee and obtained by WIRED) place PROMIS in the hands of various Canadian government agencies. These documents include two letters to Inslaw from Canadian agencies requesting detailed user manuals – even though Inslaw has never sold PROMIS to Canada. Canadian officials now claim the letters were in error.

And, of course, the software was transferred to Rafael Etian's anti- terrorism unit in Israel. The DOJ claims it was the LEAA version, but former Israeli spy Ben Menashe and others claim it was the 32-bit version. According to Ben Menashe, other government departments within Israel also saw PROMIS, and this time the pitchman was Dr. Earl Brian. In a 1991 affidavit related to the bankruptcy proceedings, Ben Menashe claimed: "I attended a meeting at my Department's headquarters in Tel Aviv in 1987 during which Dr. Earl W. Brian of the United States made a presentation intended to facilitate the use of the PROMIS computer software."

"Dr. Brian stated during his presentation that all U.S. Intelligence Agencies, including the Defense Intelligence Agency, the Central Intelligence Agency, and the National Security Agency and the U.S. Department of Justice were then using the PROMIS computer software," Ben Menashe continued. While the credibility of his statements has been questioned, the Israeli government has admitted that Ben Menashe had access to extremely sensitive information during his tenure at the Mossad.

Asked why Israeli intelligence would have been so interested in Inslaw and PROMIS, Ben Menashe said, "PROMIS was a very big thing for us guys, a very, very big thing ... it was probably the most important issue of the '80s because it just changed the whole intelligence outlook. The whole form of intelligence collection changed. This whole thing changed it." PROMIS, Ben Menashe said, was perfect for tracking Palestinians and other political dissidents.

(Ben Menashe's superior during this period was Rafael Etian, or Dr. Ben Orr, as he was known during his 1983 visit to Inslaw.)

Apparently, Israel was not the only country interested in using PROMIS for internal security purposes. Lt. Col. Oliver North also may have been using the program. According to several intelligence community sources, PROMIS was in use at a 6,100-square-foot command center built on the sixth floor of the Justice Department. According to both a contractor who helped design the center and information disclosed during the Iran-Contra hearings, Oliver North had a similar, but smaller, White House operations room that was connected by computer link to the DOJ's command center.

Using the computers in his command center, North tracked dissidents and potential troublemakers within the United States as part of a domestic emergency preparedness program, commissioned under Reagan's Federal Emergency Management Agency (FEMA), according to sources and published reports. Using PROMIS, sources point out, North could have drawn up lists of anyone ever arrested for a political protest, for example, or anyone who had ever refused to pay their taxes. Compared to PROMIS, Richard Nixon's enemies list or Sen. Joe McCarthy's blacklist look downright crude. This operation was so sensitive that when Rep. Jack Brooks asked North about it during the Iran-Contra hearings, the hearing was immediately suspended pending an executive (secret) conference. When the hearings were reconvened, the issue of North's FEMA dealings was dropped.

A Thorough Cleaning at the White House?

If the case against the Department of Justice is so solid, why hasn't anything been done? The answer is timing. The next move belongs to retired Federal

If the case against the Department of Justice is so solid, why hasn't anything been done? The answer is timing. The next move belongs to retired Federal Judge Bua, since he was given oversight by Attorney General Barr in lieu of an independent counsel. And everyone, including Judge Bua, whose non-binding report was pending at WIRED's early December deadline, seems to be waiting for the new administration. Both the Clinton/Gore transition team and House majority leader Richard Gephardt had no comment on the Inslaw case pending Clinton's inauguration.

But a source close to Bua's investigation said the retired judge may present the DOJ with a bombshell. While not required to suggest a settlement, the source believes Bua will reportedly recommend that Inslaw be given between $25 million and $50 million for its mistreatment by the DOJ. (In last-minute negotiations, Inslaw attorney Elliot Richardson held brief meetings with DOJ officials in mid-December. Richardson pressed for a settlement ranging from $25 million to $500 million, but the DOJ balked, according to newspaper reports.)

But the question remains: Can the DOJ paper over the willful destruction of a company, the plundering of its software, the illegal resale of that software to further foreign policy objectives, and the overt obstruction of justice with $25 million?

Bua's final recommendation, expected sometime before Clinton's inauguration, is that the Inslaw Affair "requires further investigation," the source said. That conclusion mirrors the House Judiciary Committee's report. Privately, many Democrats, including Gephardt, have expressed a strong desire to get to the bottom of the Inslaw case. Rep. Brooks will be pushing for yet another investigation of the scandal, this time independent of the Justice Department, according to Congressional sources. Once Bua's report is out, the next and possibly final move will be up to a new president, a new Congress, and, possibly, a renewed sense of justice.

Earl W. Brian - The Consumate Insider

Dr. Earl W. Brian has made quite a career of riding Reagan and Meese's coattails. After a stint in Vietnam, where he worked as a combat physician in the unit that supplied air support for Operation Phoenix, Brian returned to California with a chest full of ribbons and a waiting job - as Secretary of Health - with then-Governor Reagan's administration. (Operation Phoenix, a well-documented CIA political assassination program, used computers to track "enemies" in Vietnam.)

In 1974, Brian resigned his cabinet post with Governor Reagan to run for the Senate against Alan Cranston. After his defeat, Brian moved into the world of business and soon ran into trouble. His flagship company, Xionics, was cited by the Security and Exchange Commission for issuing press releases designed to boost stock prices with exaggerated or bloated information. The SEC also accused Xionics of illegally paying "commissions" to brokers, according to SEC documents.

At the close of the Reagan governorship, Brian was involved in a public scandal having to do with - surprise - stolen computer tapes. The tapes, which contained records of 70,000 state welfare files, were eventually returned - Brian claimed he had a right to them under a contract signed in the last hours of the administration. (Brian said he just wanted to develop a better way of doing welfare business.)

In 1980, Brian formed Biotech Capital Corp., a venture capital firm designed to invest in biological and medical companies. Ultimately, Brian has invested in and owned several companies, including FNN (Financial News Network) and UPI, both of which ended up in dire financial straits.

Ursula Meese, who like her husband knew Brian from the Reagan cabinet, was an early investor in Biotech, using $15,000 (borrowed from Edwin Thomas, a Meese aide in the White House and another Reaganite from California) to purchase 2,000 shares on behalf of the Meese's two children, according to information made public during Meese's confirmation hearings for Attorney General.

It is those Reagan-Meese connections that continue to drag Brian into the Inslaw affair. For why would Brian, of all people, be the recipient of stolen PROMIS? PROMIS, after all, was a major part in government automation contracts estimated at $3 billion, according to Inslaw President Bill Hamilton. That's quite a political plum.

One possibility is Ed and Ursula Meese's financial connections to Brian. Another is a payoff for Brian's role in the October Surprise Even if he manages to evade the Inslaw allegations, Brian may still be in hot water. As of this writing, Financial News Network's financial dealings were under investigation by a Los Angeles Grand Jury, according to sources who have testified before it. - RLF

What A Surprise!

Earl W. Brian says he wasn't in Paris in October 1980, but investors were told a different story

As Inslaw President Bill Hamilton moved his company from non-profit status to the private sector in 1980, Ronald Reagan was running for President, negotiations for the release of the American hostages in Iran had apparently hit a snag, and Dr. Earl W. Brian was touring Canada touting stock in his newly acquired Clinical Sciences Inc.

History records that the hostages were released as Ronald Reagan took the Presidential oath of office, and that shortly thereafter, Inslaw received a $9.6 million contract from the Department of Justice. At the same time, Earl Brian was appointed to a White House post to advise on health-care issues. Brian reported directly to Ed Meese. He also arranged White House tours to woo investors in his government contracting company, Hadron Inc., according to a Canadian investment banker who took a tour.

But these seemingly random historical connections between Inslaw, Hadron, the Reagan White House and Earl Brian take on a new meaning when considered in light of the "October Surprise," the persistent allegation that the Reagan campaign negotiated with Iranian officials to guarantee that US hostages would not be released before Reagan won election in 1980.

The October Surprise theory hinges in part on alleged negotiations between the Reagan campaign and the Iranians on the weekend of Oct. 17-21, 1980, in Paris, among other places.The deal, according to former Iranian President Abol Hassan Bani-Sadr, ex-Israeli spy Ari Ben Menashe, and a former CIA contract agent interviewed by WIRED, included the payment of $40 million to the Iranians.

According to several sources, Earl Brian, one of Reagan's close advisors, made it quite clear that he was planning to be in Paris that very weekend. Ben Menashe, who says he was one of six Israelis, 12 Americans and 16 Iranians present at the Paris talks, said, "I saw Brian in Paris."

Brian was interviewed by Senate investigators on July 28, 1992, and denied under oath any connection with the alleged negotiations. He told the investigators he did not have a valid passport during the October 1980 dates. But according to court documents and interviews, Brian told Canadian investors in his newly acquired Clinical Sciences, Inc., that he would be in Paris that weekend. Brian acquired controlling interest in Clinical Sciences in the summer of 1980. Clinical Sciences was then trading at around $2 a share. Brian worked with Janos P. Pasztor, a vice president and special situations analyst

with the Canadian investment bank of Nesbitt, Thomson, Bongard Inc., to create a market of Canadian investors for the stock.

Pasztor later testified in court documents that Brian said he would be in Paris the weekend of October 17 to do a deal with the Pasteur Institute (a medical research firm).

Two other brokers, Harry Scully, a broker based in Halifax, Nova Scotia, and John Belton, a senior account executive with Nesbitt-Thomson from 1968 to 1982 who is suing Nesbitt-Thomson and Pasztor for securities fraud, also claim that they were told that Brian was in Paris that weekend.

But if Brian went to Paris to see the Pasteur Institute, he seems to have missed his appointment. An investigation by the Royal Canadian Mounted Police into Clinical Sci-ences stock transactions revealed that the Pasteur Institute had never conducted business with, or even heard of Brian.

When asked by WIRED to elaborate on Brian's 1980 trip, Pasztor said, "These are political questions and I don't want to become involved." He refused further comment.Brian contends that the dates of his trip were in error and that he went to Paris in April 1981, not October 1980. But the passport he turned over to Senate investigators did not contain a French entry or exit stamp for April 1981.

Through his lawyers, Brian refused to be interviewed for this story. - RLF

Earl W. Brian: Closet Spook?

Michael Riconosciuto, a computer programmer and chemist who surfs the spooky fringe of the guns-'n'-money crowd, is currently serving a federal prison sentence for drug crimes. From his jail cell he has given several interviews claiming knowledge of Inslaw and the October Surprise (he also claims his jail term is the DOJ's way of punishing him for his knowledge). Much of what he claims cannot be verified, other statements have failed to be veri-fied conclusively.

But prior to his arrest in 1991, Riconosciuto provided the Hamiltons with an affidavit that once again brought Brian into the Inslaw picture. "I engaged in some software development and modification work in 1983 and 1984 on proprietary PROMIS computer software product," he stated. "The copy of PROMIS on which I worked came from the US Department of Justice. Earl W. Brian made it available to me through Wackenhut (a security company with close FBI and CIA connections) after acquiring it from Peter Videnieks, who was then a Department of Justice contracting official with the responsibility for PROMIS software. I performed the modifications to PROMIS in Indio, Calif.; Silver Springs, Md.; and Miami, Fla."

The modifications included a telecommunications "trap door" that would let the US Government eavesdrop on any other organization using the pirated software, Riconosciuto said.

Videnieks and Brian both told House investigators that they did not know Riconosciuto. After Riconosciuto was interviewed by House investigators, Videnieks refused to give Congress further interviews.

Although Brian denies any involvement with Inslaw or Riconosciuto, the House Judiciary Committee received a report from a special task force of the Riverside County, Calif., Sheriff's Office and District Attorney, stating that on the evening of Sept. 10, 1981, arms dealers, buyers and various intelligence operatives gathered at the Cabazon Indian Reservation near Indio, Calif., for a demonstration of night warfare weapons. The demonstration was orchestrated jointly by Wackenhut and the Cabazon Indian tribe. (Many published reports allege that the Wackenhut/Cabazon joint venture served as a weapons fencing operation for Oliver North's Iran- Contra dealings.)

According to Indio city police officers hired to provide security, those attending included Earl W. Brian, who was identified as "being with the CIA," and Michael Riconosciuto. - RLF

US Deputy Attorney General Jensen Lost Once To Inslaw

Could It Be He Wanted to Even The Score? At the time of its inception, PROMIS was the most powerful program of its type. But a similar program, DALITE, was developed under another LEAA grant by D. Lowell Jensen, the Alameda County, Calif., District Attorney. In the mid-1970s, the two programs vied for a lucrative Los Angeles County contract and Inslaw won out.

Early in his career, Attorney General-to-be Edwin Meese worked under Jensen at the Alameda County District Attorney's office. Jensen was later appointed as Deputy Attorney General into Meese's Justice Department.

C. Madison "Brick" Brewer, accused by the House Judiciary Committee of deliberately misappropriating PROMIS, testified in federal court that everything he did regarding Inslaw was approved by D. Lowell Jensen, the same man who once supervised DALITE.

Was Israel's PROMIS to Crush the Infitada?

Asked why Israeli intelligence would have been so interested in Inslaw and PROMIS, ex-Israeli spy Ari Ben Menashe said: "PROMIS was a very big thing for us guys, a very, very big thing ... it was probably the most important issue of the '80s because it just changed the whole intelligence outlook. The whole form of intelligence collection changed. This whole thing changed it." Why? PROMIS, Ben Menashe said, was perfect for tracking the Palestinian population and other political dissidents.

Did Oliver North Use PROMIS?

Apparently, Israel was not the only country interested in using PROMIS for internal security purposes. Lt. Col. Oliver North also may have been using the program. According to several intelligence community sources, PROMIS was in use at a 6,100-square-foot command center built on the sixth floor of the Justice Department. According to both a contractor who helped design the center and information disclosed during the Iran-Contra hearings, Oliver North had a similar, but smaller, White House operations room that was connected by computer link to the DOJ's command center.

Who Fired Inslaw's Lawyer?

As the Inslaw-DOJ battle was joined in bankruptcy court, Inslaw's chief attorney, Leigh Ratiner, was fired from Dickstein, Shapiro & Morin, the firm where he had been a partner for 10 years. His firing came after another Dickstein partner, Leonard Garment, met with Arnold Burns, then- deputy attorney general of the DOJ.

Garment was counsel to President Richard Nixon and assistant to President Gerald Ford. He testified before a Senate inquiry that he and Meese discussed the Inslaw case in October 1986, and afterward he met with Burns. Two days later Ratiner was fired.

The [illegible] of the firm's ties to the [illegible] Ratiner and his firm made [illegible] to [illegible] but WIRED has learned [illegible] Ari Ben Menashe that

The terms of the financial settlement between Ratiner and his firm were kept confidential, but WIRED has been told by ex-Israeli spy Ari Ben Menashe that Israeli intelligence paid to have Ratiner fired, and that the money was transferred through Hadron Inc., the same company that Earl Brian used to distribute illegal copies of PROMIS. Through informed sources, WIRED has independently confirmed portions of Ben Menashe's allegations.

Ben Menashe has told WIRED that he saw a memo in Israel, written in Hebrew, requesting funds for "a lawyer." He claims to have seen the memo at the office of a joint Mossad (Israeli CIA), Internal Defense Forces and Military committee specializing in Israeli-Iran relations. Israel admits that Ben Menashe handled communications at this level and therefore would have had access to such transmissions.

Ben Menashe said the money was used as Ratiner's settlement payment. "The money was transferred, $600,000, to Hadron," he said. As to why Hadron was used, Ben Menashe claims: "Because [Brian] was involved quite deeply." He said Ratiner was unaware of the source of the settlement funds.

Ratiner, contacted after the Ben Menashe interview, said he had never disclosed the amount of the separation settlement to anyone. He is limited contractually by his former firm from discussing any specifics of the firing. Asked if Ben Menashe's figures were correct, Ratiner said, "I can't comment because it would be the same as revealing them." WIRED located a deep background source who confirmed that the amount was "correct almost to the penny."

Ratiner said he was shocked at the allegations of money laundering. "Dickstein, Shapiro is the 10th largest firm in Washington and I had no reason to think it was other than reputable," he said. "Why is it that everyone who comes in contact with the Inslaw case becomes a victim?" - RLF

A Dead Journalist Raises Some Eyebrows

Among the many strong conclusions of the "House Judiciary Committee Report on the Inslaw Affair" was this rather startling and brief recommendation: "Investigate Mr. Casolaro's death."

Freelance reporter Danny Casolaro spent the last few years of his life investigating a pattern which he called "The Octopus." According to Casolaro, Inslaw was only part of a greater story of how intelligence agencies, the Department of Justice and even the mob had subverted the government and its various functions for their own profit.

Casolaro had hoped to write a book based on his reporting. His theories, which some seasoned investigative journalists have described as naive, led him into a Bermuda Triangle of spooks, guns, drugs and organized crime. On August 10th, 1991, he was found dead in a Martinsburg, W. Va., hotel room. Both wrists were deeply slashed.

Casolaro's death has only deepened the mystery surrounding Inslaw. Among the more unusual aspects of his death: He had gone to Martinsburg to meet an informant whose name he never revealed. He had called home the afternoon before his death to say he would be late for a family gathering. Martinsburg police allowed his body to be embalmed before family members were notified and warned hotel employees not to speak to reporters. The hotel room was immediately scrubbed by a cleaning service. Casolaro had told several friends and his brother that if anything ever happened to him, not to believe it was an accident. And his notes, which witnesses saw him carry into the hotel, were missing.

His death was ruled a suicide by Martinsburg and West Virginia authorities several months later. Friends, relatives and some investigators still cry foul.

A source close to retired Federal Judge Nicholas Bua (the Bush Administration appointee who is investigating Inslaw) said Bua will not come to any conclusions regarding Casolaro's fate. "I don't know if he committed suicide or if it was murder," the source said. "But the evidence is consistent with both theories. There are things that bother me but ... certainly no one can be indicted on the evidence that is available."

What does that mean? Either an independent investigation drums up more evidence, or the case may never be solved.

The House Judiciary Committee may have written what could be called the final word on Danny Casolaro's inexplicable death: "As long as the possibility exists that Danny Casolaro died as a result of his investigation into the Inslaw matter, it is imperative that further investigation be conducted." - RLF

InslawGate?

Elliot Richardson, President Nixon's former attorney general (he was fired when he refused to fire Archibald Cox during the Watergate scandal) has been a counsel to Inslaw for nearly 10 years (he retired this January). In a Oct. 21, 1991 New York Times Op Ed, Richardson wrote: "This is not the first time I have had to think about the need for an independent investigator. I had been a member of the Nixon Administration from the beginning when I was nominated as Attorney General in 1973. Confidence in the integrity of the Watergate investigation could best be insured, I thought, by entrusting it to someone who had no prior connection to the White House. With Inslaw, the charges against the Justice Department make the same course even more imperative.

"When the Watergate special prosecutor began his inquiry, indications of the President's complicity were not as strong as those that now point to a broad conspiracy implicating lesser Government officials in the theft of Inslaw's technology."

A Well-Covered Coverup?

The House Committee Report contained some no-holds-barred language on the issue of stonewalling:

"One of the principle reasons the committee could not reach any definitive conclusion about Inslaw's allegations of a high criminal conspiracy at Justice was the lack of cooperation from the Department," the report states. "Throughout the two Inslaw investigations, the Congress met with restrictions, delays and outright denials to requests for information and to unobstructed access to records and witnesses.

"During this committee's investigation, Attorney General Thornburgh repeatedly reneged on agreements made with this committee to provide full and open access to information and witnesses ... the Department failed to provide all the documents subpoenaed, claiming that some of the documents ... had been misplaced or accidentally destroyed."

Rep. Jack Brooks and the House Committee On the Inslaw Case

The string of lawsuits and widening allegations caught the eye of House Judiciary Committee Chairman Jack Brooks, D-Texas, who in 1989 launched a three-year investigation into the Inslaw affair. In the resulting report, the Committee suggested that among others, Edwin Meese, while presidential counselor and later as attorney general, and D. Lowell Jensen, a former assistant and deputy attorney general and now a U.S. district judge in San Francisco, conspired to steal PROMIS.

"There appears to be strong evidence," the report states, "as indicated by the findings in two Federal Court proceedings as well as by the committee

investigation, that the Department of Justice 'acted willfully and fraudulently,' and 'took, converted and stole,' Inslaw's Enhanced PROMIS by 'trickery fraud and deceit.' "

"While refusing to engage in good faith negotiations with Inslaw," the report continues, "Mr. Brewer and Mr. Videnieks, with the approval of high- level Justice Department officials, proceeded to take actions to misappropriate the Enhanced PROMIS software."

Furthermore, the report states, "several individuals have stated under oath that the Enhanced PROMIS software was stolen and distributed internationally in order to provide financial gain to Dr. Brian and to further intelligence and foreign policy objectives for the United States."

Rep. Brooks told WIRED that the report should be the starting point for a grand jury investigation. The owners of Inslaw, Brooks said, were "ravaged by the Justice Department ... treated like dogs."

ORGANIZE NEW 10 MILLION DOLLAR MINING COMPANY

American and Canadian interests already linked in Noranda Mines, Ltd., an important Canadian corporation with assets at the close of 1928 in excess of $14,000,000, have joined in the formation of the International Mining company, a $10,000,000 corporation, the purpose of which will be to acquire and develop through subsidiaries metalliferous properties in Canada. Arthur Cutten and Silas H. Strawn of Chicago are directors.

Int'l Mining Offers Stock

Lehman Bros. are offering 63,505 shares of common stock of International Mining Corporation for sale at $11 a share. This circular which is quite complete and one of the few as yet issued under the new security law states that appraisal by Arthur Young & Company, accountant, shows the isted securities held by International Mining Corporation June 14, 1933, had a quoted value of $4,143,754. Assuming that all the 63,505 shares offered are sold the proceds of the sale together with the quoted value of the listed shares June 14, cash on hand and unlisted shares at cost would have given the 400,000 shares that would be outstanding a value of $13.24 a share, the circular states.

1933-07-05-the-brooklyn-daily-eagle-pg-28-clip-intl-mining-stock

International Mining Corporation is organized to search for mining properties and to acquire interests in other mining enterprises but is permitted to invest in other than mining securities by its charter. Its officers are mainly mining engineers. H. W. Chadbourne is president and Thomas L. Chadbourne, chairman of the board. A representative of Lehman Brothers is to be elected to the board of directors.

Operating expenses of the corporation in 1932 were $109,497. The purpose of the present issue is to provide the company with additional funds as the management feels that there are now desirable opportunities for the investment of additional moneys in mining and allied enterprises. The present issue if all sold will net the corporation $583,307.

Retired Mine Executive, Houghton Native, Dies

NEW YORK, Oct. 27 (AP)—Michigan-born Humphrey Wallingford Chadbourne, retired mining executive, died yesterday at the age of 66.

Chadbourne, a native of Houghton, Mich., was president of the International Mining corporation, until retirement several years ago.

The firm mined gold and copper in the United States, Canada, Mexico and South America.

Chadbourne also had been a director of Noranda Mines, Canadian subsidiary of Zonite Products corporation, and the American Commercial Alcohol corporation and the Butterick company.

Sunset Oil and Intl. Mining In Merger Deal

LOS ANGELES, March 22—Sunset Oil Company and International Mining Corporation today announced the execution of a merger agreement.

Sunset markets petroleum products in the Bay Area through a wholly owned subsidiary, the Craig Oil Company.

The merger plan, subject to final stockholders' approval at the annual meetings to be held in May, provides for the conversion of each share of Sunset common stock into three shares of the common stock of International Mining.

The agreement further provides for the change of International's name otSun set International Petroleum Corporation.

International Mining was originally founded as a natural resources company but has since become an investment company, holding substantial mining and other related natural resource securities.

Officials stated the merger would provide International with an opportunity to use its relatively dormant capital for development and expansion and place Sunset in a favorable position for acquisition of producing properties.

Proposed officers for the merged organization, to be called Sunset International Petroleum Corp., are J. Dave Sterling, president; Morton A. Sterling, executive vice president; George C. Sheahan, financial vice president; and W. H. Tietz, secretary-treasurer. They presently hold the same positions in Sunset.

Pittsburgh Business

Pennroad Corp., Investment Trust, Enlarges Holdings in This District

By Hi Howard

THE PITTSBURGH district has several business ties—direct and indirect—with the Pennroad Corp., the New York investment trust which has just acquired a substantial interest (along with South American Gold & Platinum Co.) in National Department Stores Corp.

Of major interest in local merchandising circles, National Department Stores owns both the Frank & Seder and Rosenbaum department stores here.

One of Pittsburgh's long-standing connections with Pennroad is that this investment company controls the Pittsburgh & West Virginia Railway, which has its headquarters here.

Mr. Howard

Another is that a number of Pittsburghers still own Pennroad stock. But this Pitsburgh financial interest in Pennroad is not nearly as strong as it once upon a time. The Mellon family, largely as a result of investments made by the late R. B. Mellon, father of Richard K. Mellon, had a fairly substantial holding in this company until several years ago.

But these personal holdings by members of the Mellon family, it's reported, have been sold, and the Mellon interest in Pennroad is either gone completely, or comparatively small and indirect.

MAY RESIGNED

Until recently, three of Pennroad's 11 directors were Pittsburghers. But one of the trio, Herbert A. May, who is also senior vice president of the Westinghouse Air Brake Co. here, resigned when he became a director of the Nickel Plate Railroad.

Those from this area sill on the Pennroad board are William T. Kilborn and F. Brian Reuter. Kilborn is president of the Flannery Bolt Co. and the Fort Pitt Manufacturing Co., and a director of the Pittsburgh & West Virginia Railway and of the National Union Fire Insurance Co. here. Reuter is vice president of the Mellon National Bank & Trust Co., and also a director of the Pittsburgh & West Virginia.

PRR 'CREATION'

The Pennroad Corp. started life, back in the Summer of 1929, as a brainchild of the late W. W. Atterbury, president of the Pennsylvania Railroad.

Atterbury and other PRR officers were concerned about the "consolidation" moves made by other Eastern railroads—notably the New York Central and Baltimore & Ohio—and came to the conclusion that the PRR had to protect its interests. They also had an eye on the Van Sweringen efforts to put together another major Eastern railroad system with the Nickel Plate as a nucleus.

At the same time, they had to keep in mind that the Pennsylvania had little hope of getting Federal approval for the purchase of a controlling interest in competing railroads.

SEPARATE CONCERN

The Van Sweringen brothers, of Cleveland, showed the way out of this dilemma by forming their Allegheny Corp. early in 1929, as a device for owning and controlling railway properties.

The PRR management arranged for the formation of Pennroad, as a separate company, to enable PRR stockholders to make investments in the transportation field which would not only be sound and profitable investments, but which would also serve to protect their interests as PRR stockholders.

Such protection of their interests, it was made clear, would include the purchase of railroad securities to prevent them from falling into hands which might be unfriendly to, or at least uncooperative with, the Pennsylvania.

VOTING TRUST

And to make assurance doubly sure that this would be Pennroad policy, all Pennroad stock was placed in a voting trust, with three PRR directors as trustees, and all but one of the eight directors were also PRR directors. And the eighth director was a former PRR treasurer.

Pennroad sold 80 per cent of its stock to PRR stockholders, at $15 a share, and raised a total of $91,125,000. A large chunk of this money was used to buy a controlling interest in the Detroit,Toledo & Ironton Railroad, formerly owned by Henry Ford and some associates, thus safeguarding the PRR's entry into the profitable Detroit area.

Another chunk was used to buy most of the stock of the Canton Co., of Baltimore, maintaining another PRR connection with a major terminal.

Pennroad also invested $17,500,000 in New Haven Railroad stocks, and more than $23,600,000 in Boston & Maine Railroad securities—both investments aimed at holding "friends" of the PRR.

BOUGHT P. & W. VA.

But Pennroad's largest investment was in 220,000 shares of Pittsburgh & West Virbinia Railroad Co., purchased from Frank E. Taplin, who tried to revive the old Gould railroad dream.

The total cost of this purchase, representing about 72 per cent of the outstanding stock, was $38,000,000. To aid in making this deal, Pennroad sold more of its own stock, and also offered additional voting trust certificates (each representing one share of stock) at $16.50 to the owners of its outstanding certificates.

The stock market crash of October, 1929, took place only a few weeks after this offer was first made. But the Pennroad stock sale was in the hands of an underwriting group, and this group made good on the whole issue, even though only about half of it was sold. Pennroad obtained a total of $44,660,000 from this new issue.

During the great depression of the early Thirties, the value of Pennroad's railroad holdings dropped sharply. Pennroad stock sold as low as $2 a share.

AFFILIATED WITH PRR

But Pennroad's close affiliation with the PRR continued until 1940, or until after the expiration of the voting trust agreement which kept majority control of Pennroad stock in the hands of PRR.

Since early 1941, none of the Pennroad directors has been a PRR director, and in that same year, Pennroad registered with the Securities & Exchange Commision as an investment trust, under the requirements of the Investment Co. Act of 1940.

At the same time, the new Pennroad management started a diversification program, aimed at switching a large part of its holdings out of railroad securities into other fields of business, as opportunity offered.

SOLD HOLDINGS

Pennroad has sold its holdings in the Detroit, Toledo & Ironton Railroad to the Pennsylvania, and also has disposed of its stock in the Wheeling & Lake Erie. The cash obtained from these and other sales has been invested largely in utilities, and also in oil and gas stocks, as well as in other interests.

But Pennroad still holds a controlling interest in the Pittsburgh & West Virginia here, which has been a profitable investment during recent years.

LEGAL ACTION

Pennroad also obtained more than $12,000,000 as a result of a suit filed by a group of Pennroad stockholders against the Pennsylvania Railroad in early 1943. This marathon legal action, known as the Overfield-Weigle case, charged the PRR officers and directors were responsible for losses reputedly totaling more than $95,000,000 as a result of Pennroad's investments during 1930 and 1931.

After four years of litigation, a compromise settlement was reached, and the PRR made a payment of $15,000,000. But out of this payment, 16 attorneys and law firms, and three members of the stockholders committee were awarded fees totaling $2,445,000.

Pennroad now has total assets of nearly $100,000,000, with about 5,000,000 shares outstanding. The price range on the American Stock Exchange this year has been from $16.12 to $18.75, and the stock sold last year Friday for about $17.60 a share.

Rosenbaum's, Frank & Seder in Unit

New Group Controls Chain of 16 Stores

1955-04-25-pittsburgh-sun-telegraph-pg-1-4-clip-new-group-16-stores

NEW YORK, April 25.—(AP.)—Control of National Department Stores Corp. has been acquired by a group headed by South American Gold & Platinum Co. and Pennroad Corp., Lewis B. Harder, president of South American, said today.

National Department Stores, with annual sales of 75 million dollars, owns and operates a chain of 16 stores in major cities in several sections of the country.

Two Pittsburgh subsidiaries of National are Frank & Seder and Rosenbaum Co.

Harder said the group now in control owns more than 50 per cent of the 782,140 shares of National Department Stores' stock.

A few days ago, it was disclosed that South American had acquired 100,000 shares.

Harder said today that South American and Pennroad Corp. since have bought 93,000 additional shares, the entire holdings of the Schwartz and Sadowsky families who have been identified with the chain for many years.

ANOTHER OFFER

South American bought 43,000 of these shares and Pennroad 50,000, he said. Associates of the two companies also own more than an additional 175,000 shares, according to Harder. The South American group has made an offer to certain large stockholders of National to acquire 91,000 shares more.

It is expected that Harder and Edward A. Merkle, executive vice president of Pennroad, will join the board of National. Harry A. Schwartz will continue as president.

Schwartz declared today:

"My family and myself, believing that it was in the best interests of the corporation, have agreed to sell our holdings to the group. They have asked me to carry on as president and director, which I have consented to do."

"It is their hope and the hope of the management that under new ownership the company will continue to progress and expand. The groupe has indicated a desire to develop National as a larger and more important department store company."

National has stores in Portland, Ore.; Morrisville, Pa.; Trenton, N. J.; Memphis; Atlanta; San Antonio; Houston; Baton Rouge; four in Cleveland, two in Wheeling, W. Va., and the two in Pittsburgh.

Harder became president of South American last July. Since then, the company, which has produced gold and platinum in Colombia since 1917, has undergone a major diversification of its investments in Latin America.

Pennroad Corp., which began as a railroad holding company, in recent years has become a general investment company, with holdings in a wide range of fields.

Harder said any future plans for National cannot be discussed at this time, pending an intensive engineering survey of the properties.

National's earnings for 1954 were reported at $422,905 or 54 cents a common share, the lowest in many years. The chain's profits have dropped sharply since reaching a high of $4,267,821 or $5.45 a share in 1947.

(The Mellon family formerly had a substantial interest in the Pennroad Corp., and this investment trust still has a little Pittsburgh money in its financial bloodstream. Two of Pennroad's directors are Pittsburghers — William T. Kilborn, president, Flannery Bolt Co., and F. Brian Reuter, vice president, Mellon National Bank & Trust Co. For details, see Hi Howard's Pittsburgh Business column on the financial page.)

Department Stores Chain Reorganized

Rosenbaum Co., Frank & Seder Are Subsidiaries Here

NEW YORK, April 24 (AP)—Control of National Department Stores Corporation has been acquired by a group headed by South American Gold & Platinum Company and Pennroad Corporation, Lewis B. Harder, president of South American, said today.

National Department Stores, with annual sales of 75 million dollars, owns and operates a chain of 16 stores in major cities including two in Pittsburgh and two in Wheeling, W. Va.

Operations of two Pittsburgh subsidiaries, Frank & Seder and Rosenbaum Company, were affected by the 15-months strike of truck delivery workers, which was settled last month.

Harder said any future plans for National cannot be discussed at this time, pending an intensive engineering survey of the properties.

Harder said the group now in control owns more than 50 percent of the 782,140 shares of National Department Stores' stock.

A few days ago, it was disclosed that South American had acquired 100,000 shares.

Harder said today that South American and Pennroad Corporation since have bought 93,000 additional shares, the entire holdings of the Schwartz and Sadowsky families who have been identified with the chain for many years.

National Aims For Volume

NEW YORK, July 8.—(AP.)—Frank L. Kellogg, recently elected chairman of National Department Stores, painted a grim picture today of the chain's operations before the new management that he heads took over.

Kellogg became chairman May 15 and presided at the annual stockholders' meeting yesterday. In the first four months of the chain's fiscal year beginning Feb. 1, he said, losses were running 15 per cent greater than in the same period of 1954, although sales were slightly higher.

Of the 17 stores in the National chain, said Kellogg, only seven showed sales increases between Feb. 1 and May 31, and the other ten failed to match their year-ago performance. Only three finished out of the red, he added.

May Sell Stores

Kellogg told stockholders that National must "secure for ourselves a greater share of the retail business in each city or community where we operate . . . your new management intends to strengthen our organization . . . (and) train our buyers to do a better job." Stores that fail to show definite promise may be sold, he said.

At a directors' meeting after the stockholders' session, Kellogg was elected to the additional post of president, succeeding Harry H. Schwartz. Lewis B. Harder, president of South American Gold & Platinum Co., was elected to the newly created post of financial vice president and George Lehrman was named secretary and treasurer.

Pass Dividend

South American Gold & Platinum recently acquired control of National.

Directors took no action on the common stock dividend usually declared at this time. The company had previously paid 25 cents at quarterly intervals. Kellogg said the company had not earned its dividends in 1953 and operated at a loss last year.

National Department Stores units here include Frank & Sedet of Pittsburgh Inc., and Rosenbaum Co here

Today In Business

The Board of Directors of The Pennroad Corporation has announced that George W. Bovenizer, formerly chairman, has been elected honorary chairman of the Board. To fill the vacancy, Bradley Gaylord, formerly president, was elected chairman of the board and **Edward A. Merkle**, of Haworth, was elected president and chief executive officer.

Merkle started his career as a page boy on the floor of the New York Stock Exchange while attending New York University. Prior to joining the Pennroad organization, he was associated with Mitchell, Hutchins & Company. Merkle came to Pennroad January 1, 1949, was elected a vice-president in early 1951 and became a director in 1953.

Besides being on the Pennroad Board, he is a director of Drewrys, Ltd., National Department Stores, Rockland Light & Power and the South American Gold & Platinum Company.

In addition to his business activities, Merkle is a member of the Board of Trustees of the Jacob A. Riis Neighborhood Settlement in New York, was one of the organizers of R. I. A. L., Religion in American Life and presently is a member of the Episcopal Bishop's Committee for the Diocese of Newark. Recently he has served in Haworth as chairman of Community Chest and National Foundation for Infantile Paralysis drives.

NEW YORK — Stockholders of the **National Department Stores Corp.** authorized the board of directors to sell all or any part of the firm's five department stores. The meeting was told, however, that the authorization does not mean the stores must be sold, and Frank L. Kellogg, president and chairman of the board, said that no active negotiations were under way. The firm's loss in the fiscal year ended Jan. 31, Kellogg announced, was only $200,000, compared with a loss of $1,236,000 a year ago. Among stores the firm operates are **Rosenbaum Co.** and **Frank & Seder**, both in Pittsburgh, and **Goldberg Corp.**, in Morrisville, Pa.

CALL FOR PROPOSALS FOR PURCHASE OR LEASE OF AIRPORT LAND

The City of El Paso will receive sealed proposals for purchase or lease of the following parcel of land situated near the Airport, for light industrial development: bounded on the south by FM 2233, on the west by the east line of the property leased to International Mining Corporation, on the north by the south line of the Public Service easement, and on the east by a north-south line located so as to include 50 acres, more or less.

Detailed requirements for proposals are given in written instructions, a copy of which may be obtained from the City Clerk.

Sealed proposals must be filed with the City Clerk by 9:30 a. m. on July 5th, 1957, at which time they will be opened and read at the meeting of the City Council. Proposals must be accompanied by a bond or cashier's or certified check in the amount of $1,000, as a guaranty that the successful bidder will comply with his proposal if accepted.

The City reserves the right to reject any or all proposals and to negotiate for agreement on the final terms of the contract.

J. M. HERRERA,
City Clerk

51-Year-Old Frank & Seder Closing Doors

400 Employes Told Wednesday Will Be Their Final Day

Frank & Seder—department store in business in Downtown Pittsburgh for 51 years—plans to close its doors Wednesday, William Onasch, president, said yesterday.

The department store yesterday gave employes a week's notice, which will keep them on the payroll through January 2. However, some of the 400 workers will stay longer to help liquidate the operation, Mr. Onasch added.

The store president blamed an "unlivable" rental situation for the liquidation.

See Hungerford's cartoon, "Old Friends," on Page 6.

100 Landlords

Rent adds up to a bigger figure than Frank and Seder wants to pay and some 100 different landlords control the land. The store found it impossible to negotiate a lower rental.

In October, Frank & Seder notified the landlords it would terminate its lease April 30. The seven-story building, which the store built in 1918, will become the property of the landlords on that date.

Offered for Sale Before

Its fate will depend on what they can do with it, Mr. Onasch pointed out. Mean-

(Continued on Page 5, Col. 4)

Frank & Seder Closing Doors

(Continued From Page 1)

while, Frank & Seder is working on plans for liquidating its inventories.

The firm has been up for sale for some time.

The department store was owned by National Department Stores, owner of a number of similar stores in large cities across the country.

Several years ago, control of National moved into the hands of financiers more interested in mining and natural resources than department stores. They started selling department stores in June, 1955, and buying oil, natural gas and metal mining properties.

Last June, the company changed its name to International Mining Corporation.

Baltimore's Business

BY JOHN T. WARD

Control Of Canton Co. Sold

Control of The Canton Company of Baltimore has been sold by the Madison Fund, Inc., to the International Mining Corporation.

The property has been on the market for several years, and a deal with the Maryland Port Authority, under negotiation for several months, was abandoned last summer when no agreement on price could be made.

Diversified Investment

International Mining, formerly known as National Department Stores Corporation, has divested itself of such operations and diversified into natural resource properties, etc. It has a one-third interest in Placer Development, Ltd., of Canada, and a one-quarter ownership of natural gas royalties, minerals and fee properties in southern Louisiana along the Gulf Coast. International Mining is controlled by South American Gold and Platinum Company, of which Lewis B. Harder is the head.

Frank L. Kellogg, International Mining president, said that "with acquisition of the Canton Company and recent sale of the firm's last department store, the firm has further extended its operations in natural resources and allied fields."

Madison Fund's president, Edward A. Merkle, said the sale of Canton "represents disposition of the last special situation and controlled affiliate which had its origin in a connection with the Pennsylvania Railroad many years ago. The transaction for all practical purposes will complete our transition to full diversification in securities with an established market."

Watt To Manage

Canton is to be operated as a subsidiary under Herbert J. Watt who has been president of the local company since 1955.

Prospects of heavier imports of ore as domestic reserves decline enhance the value of the piers of The Cottman Company, a part of the Canton properties, Mr. Kellogg said. The Cottman piers now handle more than half of public pier ore imports here.

Madison Fund holds 50,000 shares of International Mining in its portfolio.

Canton had an estimated profit of $922,000 in 1959. In 1958, its net income was $915,873 on gross revenue of $7,697,992. It has assets of about $15,000,000.

Financial Details

International Mining in taking up the 92 per cent ownership of Canton by Madison will pay $25 per share. An offer also will be made to other Canton stockholders.

Madison Fund holds 342,500 shares and the entire purchase will involve about $10,850,000. Financing for the purchase consists of $3,000,000 bank loans and 10-year notes to Madison Fund. The transaction is subject to approval of International Mining stockholders and governmental regulatory bodies.

Canton's history is a part of Baltimoreana, a harbor tract of about 2,000 acres acquired by Capt. John O'Donnell, who became wealthy in Clipper ship trading and named the area for the Chinese port. The company was formed in 1828. The railroad was not built until the early 1900's to become an important link from its piers to other railroads serving this city.

Share Distribution

Pennroad once owned 399,500 shares of Canton after a 20-for-1 split in 1957 and Madison Fund (the name was changed in 1958) held 342,500 shares according to its latest report. The minority holdings include some Canton shares which were taken up by employees under a stock-option plan Of Canton's authorized 450,000 shares, there are 433,170 outstanding.

Pennroad was originally formed in 1929 by officers of the Pennsylvania Railroad as a transportation holding company. It bought control of Canton, then a Baltimore-owned company. The tie with Pennsy was cut in 1939, and in 1957 Pennroad became a regulated closed-end investment firm.

Baltimore's Business

BY JOHN T. WARD

Sale Of Canton Co. Outlined

Purchase of majority stock interest in the Canton Company of Baltimore by the International Mining Corporation which was announced last week will be a much better deal for shareholders than that offered some months ago by Maryland Port Authority.

The latter's offer would have resulted in $19.58 per share for Canton's stockholders in contrast to $25 per share from International Mining, according to Herbert J. Watt, president of Canton, who will continue to manage the company and its subsidiaries, Canton Railroad Company and The Cottman Company. There are 433,195 shares outstanding.

Port Authority's Offer

The Maryland Port Authority's offer was $13,100,000 but entailed deductions of $4,627,380, leaving $8,472,620 for the stockholders.

In the State body's offer for Canton's assets was the proviso that two special items be taken care of: $974,380 in income taxes (Canton lost a Tax Court suit involving $851,875 in Federal income taxes), and still owed $3,653,000 on a note, originally $5,000,000, which money had been borrowed for a special dividend to the corporation which controlled it, then the Pennroad Corporation but now called Madison Fund, Inc.

Madison, an investment holding firm which wished to rid itself of management obligations, decided to sell Canton. It owns 342,500 shares and once held 57,000 more. For these blocks of stock, the offer of $25 per share was made.

Additional Offer

International Mining Corporation is seeking to diversify its investments. The offer for Canton's stock will result in operating the Baltimore company and assuming its obligations, including those which the Maryland Port Authority, in its bid, would not take over.

Apart from this, Mr. Watt said in a special letter to stockholders, a provision has been made to pay $26.50 for the remaining shares in the hands of others. This would be an additional $892,917 to the stockholders if the offer is taken up.

The grand total to stockholders would be $10,880,417 in contrast to the $8,482,620 net in the Maryland Port Authority offer.

The offer by International Mining is subject to its stockholders and regulatory commissions. The purchase will be financed by $3,000,000 bank loans and ten-year notes to Madison Fund.

Kellogg Is Chairman Of Canton Company

Frank L. Kellogg, president of International Mining Corporation, has been elected board chairman of the Canton Company of Baltimore, wholly owned subsidiary of International Mining, at a meeting of Canton's Board of Directors.

Prior to his appointment in May, 1955 as president of National Department Stores Corporation, from which International Mining Corporation evolved in June, 1958, Mr. Kellogg was associated with John Wanamaker New York and Philadelphia as executive vice president.

International Mining also owns 31 per cent of the outstanding shares of Placer Development, Ltd., a Canadian mining concern with world-wide interests, and a 25 per cent interest in 275,000 acres along the Gulf Coast of Southern Louisiana consisting of natural gas and oil royalties, mineral interests and fee properties.

Shields Is Elected To Canton Board

Richard N. Shields, chairman and president of the Pittsburgh and West Virginia Railway, has been named a director of the Canton Company of Baltimore, and of its subsidiary, the Cottman Company.

R. N. Shields

A resident of Pittsburgh, he began his business career with the United States Steel Corporation, was at one time president of the Monessen Southwestern Railway, and general manager of Pittsburgh Steel Company.

Mr. Shields is head of a railroad much in the news lately. It is part of the "alphabet" route to the mid-West, being the link between the Western Maryland and the New York, Chicago and St Louis (the Nickel Plate) which have figured in consolidation plans of the Norfolk & Western Railway, with others, in connection with still more railroad plans of the Chesapeake & Ohio, the Baltimore & Ohio, the Pennsylvania, and the New York Central.

The Canton Company is controlled by International Mining Company, and was bought from the Madison Fund. International's chairman, Lewis Harder, recently went on the P. & W. Va. board. His company also has been buying heavily into that road, whose stock was hitherto widely scattered. By now it may have a majority of the stock, and be in a bargaining position differing from the original plans of the Norfolk & Western.

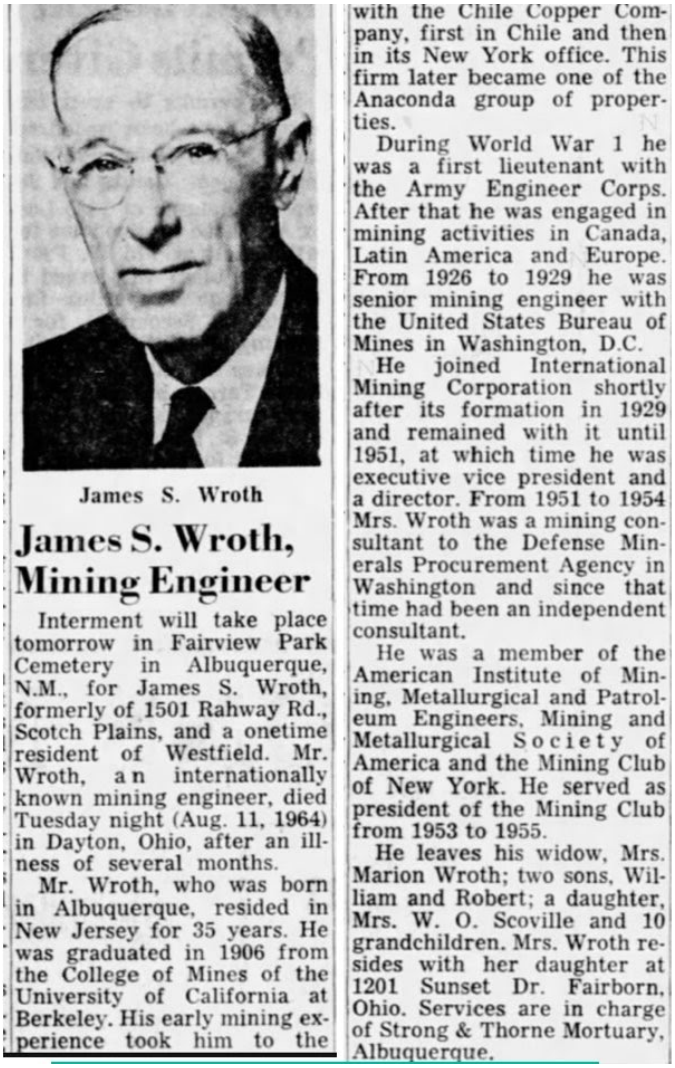
1964 -James s Wroth

1964-08-14-the-courier-news-bridgewater-nj-pg-4.jpg / https://drive.google.com/open?id=1pM7_RtiEcYQYbUgqpD9tEjyqmANxS5Fg



James S. Wroth

James S. Wroth, Mining Engineer

Interment will take place tomorrow in Fairview Park Cemetery in Albuquerque, N.M., for James S. Wroth, formerly of 1501 Rahway Rd., Scotch Plains, and a onetime resident of Westfield. Mr. Wroth, an internationally known mining engineer, died Tuesday night (Aug. 11, 1964) in Dayton, Ohio, after an illness of several months.

Mr. Wroth, who was born in Albuquerque, resided in New Jersey for 35 years. He was graduated in 1906 from the College of Mines of the University of California at Berkeley. His early mining experience took him to the with the Chile Copper Company, first in Chile and then in its New York office. This firm later became one of the Anaconda group of properties.

During World War 1 he was a first lieutenant with the Army Engineer Corps. After that he was engaged in mining activities in Canada, Latin America and Europe. From 1926 to 1929 he was senior mining engineer with the United States Bureau of Mines in Washington, D.C.

He joined International Mining Corporation shortly after its formation in 1929 and remained with it until 1951, at which time he was executive vice president and a director. From 1951 to 1954 Mrs. Wroth was a mining consultant to the Defense Minerals Procurement Agency in Washington and since that time had been an independent consultant.

He was a member of the American Institute of Mining, Metallurgical and Patroleum Engineers, Mining and Metallurgical Society of America and the Mining Club of New York. He served as president of the Mining Club from 1953 to 1955.

He leaves his widow, Mrs. Marion Wroth; two sons, William and Robert; a daughter, Mrs. W. O. Scoville and 10 grandchildren. Mrs. Wroth resides with her daughter at 1201 Sunset Dr. Fairborn, Ohio. Services are in charge of Strong & Thorne Mortuary, Albuquerque.

Two Companies Sell Rail Stock

(Dow Jones News Service)

New York, Dec. 7 — Two companies sold a total of 494,390 shares of Pittsburgh & West Virginia Railway's capital stock early in November. The company had 1,510,000 shares outstanding.

International Mining Company, New York-based firm with holdings in mining, gas, oil, and real estate, sold 351,810 of Pittsburgh & West Virginia's stock to "Institutional investors," according to L. B. Stein, vice president of International Mining.

Stein, who is also treasurer of Pittsburgh & West Virginia, said the stock was sold because International Mining will "eventually become a real estate trust."

CONTAINER TERMINAL DEDICATED

17-Acre Cargo Facility To Cost $4,000,000, Is City's First

By JOHN B. O'DONNELL, JR.

Mayor McKeldin yesterday cut a ribbon to open officially the first Baltimore marine terminal specifically designed and built for the handling of cargo containers.

Mr. McKeldin joined with officials of Sea-Land Service, Inc., and the Canton Company in dedicating the new Sea-Land terminal in the Sea-Girt area of the port.

The $4,000,000 terminal, which will not be ready for actual ship operations for several weeks, is the first phase of what Canton expects to be a $35,000,000 to $40,000,000 marine terminal in the Sea-Girt area.

Canton built the new 17-acre facility, which stands largely on created fill land, and is leasing to Sea-Land for 25 years.

Executives Present

The dedication took place during a luncheon at the new terminal facility.

Participating in the ribbon-cutting ceremonies with Mr. McKeldin were Frank Kellogg, Canton chairman; Raymond S. Clark, Canton president; and Kenneth Younger, Sea-Land executive vice president. Kellogg also is president of the International Mining Corporation, which owns Canton.

1967-05-27-the-baltimore-sun-pg-b-9-clip-sea-land-service-balt

DEDICATED—Aerial view shows the new 17½ acre Sea-Land Service, Inc. terminal in Canton which was dedicated yesterday. The Canton Company built the facility.

Sea-Land has been operating containerships from Baltimore for the last four years, using Canton's Pier 10.

Both Mr. McKeldin and Clark noted in brief remarks that the terminal is Sea-Land's second major North Atlantic port facility.

Clark noted that proposed route of the East-West expressway would take some 70 acres of Canton's "best industrial land" in East Baltimore.

Omits Reference

"It is our hope," he added, "that we can replace this land lost for industrial development by filling in and bulkheading this area so that one day the entire area will be a modern marine terminal with large acreages available for industry."

However, in reading from a prepared text he omitted a sentence which said that "with this in mind, we have been discussing methods and possible solutions with both Baltimore city officials and officials of the Maryland Port Authority."

Sea-Land now operates a weekly service to Puerto Rico and a weekly service to Europe from Baltimore. The European service has been curtailed for about two months because of a shortage of ships. The shortage resulted from inauguration of a trans-Pacific service for the Government and the temporary withdrawal of two ships shipyard repair work.

The company hopes to get European service from Ba more under way again in near future, officials said.

The new Sea-Land termi has a marshaling yard for 35-foot containers, a 50,(square-foot office and wa house building, two rail sidi and a gantry crane especia designed for the handling containers.

Spies Threatened With Guns At Australia Nickel Area

Perth (AP)—A sign that warns: "trespassers will be shot" illustrates the tension surrounding West Australia's latest glamour nickel area, Trough Wells.

Trough Wells, 35 miles north of Southern Cross and 250 miles east of Perth, is the drilling site of a company that is the current favorite of share speculators—the International Mining Corporation IMC. The eyes of the financial world have been on Trough Wells and IMC since the company's shares rocketed from 50 cents to more than $10.

The Trough Wells notice serves as a warning to spies who have been lurking near the drill sites. Another notice has been spelled out on the red earth in white stones for aerial spies —a two word message incorporating a four letter word meaning to go away.

In the past few weeks spies have chartered aircraft to plot the position of the drill holes and crept into the drill site at night to steal samples of test ore.

Others, armed with binoculars, have hidden in the bush around the drill site to spy on the drillers.

Washington Merry-Go-Round

Gerald Ford Linked to Lobby

By JACK ANDERSON

1972-07-20-the-central-new-jersey-home-news-pg-27-clip-ford-imc

WASHINGTON — It can now be documented that House GOP leader Gerald Ford had a cozy relationship with an influence-peddling Washington lobbyist who repaid Ford's favors with donations to the Republican party.

As far back as January 27, 1970, we reported that lobbyist Robert Winter-Berger was operating out of Ford's office. We then lacked evidence, however, that Winter-Berger gave campaign cash in return for Ford's intervention in federal cases.

Now, Winter-Berger has confessed his relationship with Ford, including the financial quid pro quo, in a book entitled "Washington Pay Off."

Ford has denounced the book as "a bunch of innuendoes and fabrications." The Republican leader said he knew Winter-Berger slightly but could remember only a single instance in which he helped one of the lobbyist's clients. This was an immigration case which Ford said was "meritorious."

Ford's staff told us the office files contain only a half-dozen letters relating to Winter-Berger, all of them dealing with the immigration case. Said Ford's top aide, Frank Meyer, of Winter-Berger: "He was not a close friend. He was no different than dozens of people who come into the office."

Our own investigation, however, has uncovered close to 50 letters from Ford's office involving Winter-Berger. We have also turned up several cases in which Ford went to bat for Winter-Berger's clients.

Ford's Favors

Once, Winter-Berger arranged for the GOP leader to give a public endorsement to an organization seeking to standardize the world calendar. Another time, Ford helped Winter-Berger in his efforts to get a diplomatic appointment from the Nixon Administration for Francis Kellog, president of International Mining Corporation.

Despite Ford's insistence there was "no quid qro quo" in his relationship with Winter-Berger, we have obtained copies of letters Ford wrote to the lobbyist thanking him for campaign contributions.

A typical letter, written after Winter-Berger donated $500 to the GOP in 1967, declared: "Many, many thanks for your most generous contribution." The letter is signed simply, "Jerry."

Another "Dear Bob" letter, thanking Winter-Berger for $250, calls the money "wonderful help" and says Ford is "deeply grateful."

Ford's principal help to Winter-Berger was the use of his office. This enabled the lobbyist to impress his clients with his friendship with Ford.

The congressman has now denied that Winter-Berger used the office. But letters in our possession show that the lobbyist was close not only with Ford but with members of his staff.

Ford doesn't deny that Winter-Berger made donations to the Republicans but insists that none were made to him. Yet we have found Winter-Berger gave campaign contributions in ways that could be of direct help to Ford.

For example, the lobbyist gave hundreds to the Republican Finance Committee in Kent County, Mich., which happens to be Ford's home base. A 1969 letter of gratitude from the GOP county finance chairman advised Winter-Berger:

"You have become a member of a small and distinguished group of Kent County 'Pace Setters' who donate $500 or more to the Republican cause."

The letter adds significantly: "Your good friend Jerry Ford was of course, re-elected. . .Your kind of party support was a major factor."

Whiskey Caper

A veteran investigator for the House Interstate Commerce Committee has been caught running whiskey, gin and wine across interstate lines.

The arrest of the investigator, William Druhan, is all the more embarrassing because his boss, Chairman Harley Staggers, D-W.Va., is one of Congress's most determined teetotalers.

Druhan and his immediate superior, committee counsel Daniel Manelli, mindful of Stagger's abstemious ways, have kept him in the dark about the arrest for six months.

The incident occured on February 3 when Druhan bought 40 bottles of Bourbon, scotch, gin and wine for a party in Washington. Before delivering the booze, however, he crossed into Virginia on another errand.

A Virginia trooper was following him in an unmarked car. He caught Druhane near the Pentagon. The charges were dropped after Druhan passed a four-month probation without further incidents.

Asked about the episode, Druhan said he "had no intention of doing anything wrong." He acknowledged, however, that he had planned to take some of the leftover liquor into Maryland. This, too, would have broken the law.

1973-08-10-usa-state-department-memorandum-from-william-j-jordan-of-nat-sec-council-staff-for-kissinger.pdf

Memorandum From William J. Jorden of the National Security Council Staff to the President's Assistant for National Security Affairs (Kissinger)1

August 10 1973

Ten days ago, the Colombian Minister of Mines (strongly anti-American) sent to the Senate a bill that would permit expropriation of the US-owned International Mining Company without cash compensation

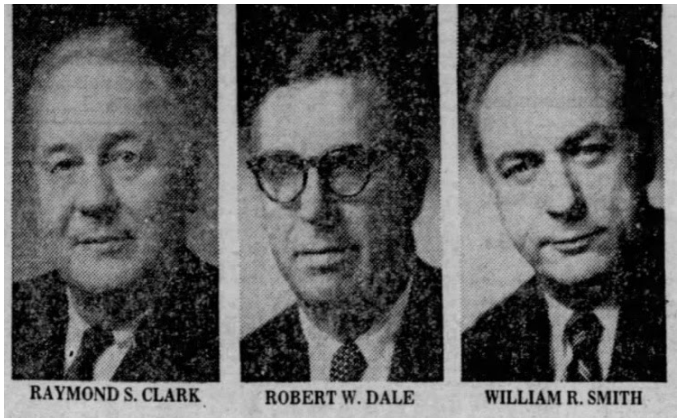
Background

IMC has been operating gold mines in Colombia for 50 years. It owns the mines and there is no contractual agreement. In recent years, the company had been losing money and was actively seeking Colombian participation, private or public. Now, with world gold prices at record highs, the company is showing a profit. I gather the company is unpopular in the region where it operates. This may be because of company actions or merely because it is foreign-owned, extractive and paternalistic. In any event, the ill feeling against the company makes expropriation attractive politically.

1976

Raymond S. Clark (born in 1913) was (and still is) a board member at Davison Chemical Company . This would imply that Robert Swan Mueller I (b1893) (who is the exclusive distributor for Davison Chemical), would be a business acquaintance. As Davison Chemical operations have been in the "lower Clinton St" area of Canton, this also suggests a long-time relationship between Robert Swan Mueller I (b1893) and the person who is now retiring as President of Canton Company .

1976-12-18-the-baltimore-sun-pg-11.jpg / https://drive.google.com/open?id=1osXwsi0MK-AmOutTM_wzIxQ-f9Pj2mb0



RAYMOND S. CLARK ROBERT W. DALE WILLIAM R. SMITH

Clark, president of Canton, will take early retirement

Raymond S. Clark, president of Canton Company since 1964, has chosen to take early retirement, according to an announcement yesterday by Lewis B. Harder, Canton's board chairman.

At a board meeting yesterday, Robert W. Dale, Jr., executive vice-president, was elected president and chief executive officer and William R. Smith, vice-president, was elected executive vice-president of the diversified, maritime-oriented company. The promotions are effective January 1.

Mr. Clark, who will turn 63 the day of his retirement, is a New York native who practiced law in Baltimore following his 1939 graduation from the Yale law school. He joined Davison Chemical Corporation in 1951 and moved to Canton Company in 1961. He will remain as a director of and consultant to Canton Company, a spokesman for the company said.

Canton Company, now a subsidiary of International Mining Corporation is in the real estate, insurance, warehousing and stevedoring businesses; it owns a marine terminal in the Canton section of Baltimore and the Canton Railroad, a switching line serving the terminal and nearby industrial installations.

"I think we've got a great thing going in this port if we don't run out of money and the appropriate governments will permit some form of dredging," the outgoing president said in an interview yesterday.

Canton Company itself, he said, is interested in the future development of its Sea Girt property, east of the main Canton Company Marine Terminal facilities, and hopes eventually to bulkhead and fill property there that is now under water to form additional berthing and backup storage area.

Under Mr. Clark, Canton Company has outgrown its office building, known as Canton House, on Water street. Last summer it reserved office space in the state's new World Trade Center, becoming the first formally committed private-sector tenant.

As for Mr. Clark's retirement plans, he said he "might try to hang out a shingle somewhere" and was looking forward to a trip to Australia.

Mr. Dale, the newly elected president and chief executive officer, became executive vice-president of both Canton Company and its Canton Railroad Company subsidiary in 1975.

Mr. Smith, Mr. Dale's replacement as executive vice-president, was elected this year to directorships of Canton Company and three subsidiaries: Canton Railroad Company, the Cottman Company and Canton Agency, Inc.

Back to the 'Sixties

Pacific Holding Corp., a conglomerate, is riding high

Reprinted by courtesy of Barron's, Oct. 24, 1977 issue

By Michael Brody

America is still a country where a high-school drop-out can start out pumping gas and end up putting together his own personal conglomerate with over $120 million in assets. To be sure, he may step on a few toes along the way and leave a few outraged shareholders (and lawsuits) in his wake. But then that tends to happen when you're an aggressive connoisseur of values. And David Murdock definitely is an aggressive connoisseur of values.

Ten days ago, Murdock's Pacific Holding Corp. announced its intention to purchase the remaining 26% minority interest in International Mining, major control of which it acquired last spring, and merge the company with a wholly owned subsidiary of Pacific. The gobbline-up of International Mining was a throwback to the good old days of the late 'Sixties: an obscure Amex holding company with interests in bricks, tiles and tin cans, total assets of $48 million and net income of $3 million, leveraging itself to the hilt to take over a Big Board mining firm boasting $89 million in total assets and net income of $5.5 million—a potential earnings stream more than adequate to service the debt on the 9% debentures used to buy it.

Pacific also disclosed the out-of-court settlement of an International Mining shareholder lawsuit, a settlement which will add $1 (and perhaps a few cents more) in cash to the $25 debenture purchase price—the debentures, listed on the Curb, are currently trading at around 21.

David Murdock

Even after upping the ante, Pacific can take pride in a bargain: the assets of International Mining, as pointed out at the time (Barron's, March 7, April 4), commanded a market value of around $35 a share. The takeover, which was not opposed by International Mining's board, was something less than arm's length; Pacific already was International's largest shareholder, with 21.4% of the stock, and Murdock had been a director for several months when the bid was made. But lawyers for the unhappy plaintiff apparently felt that this point was not likely to be worth much more than $1 in the courts.

Hackles raised

Murdock's takeover methods were raising hackles long before he hit the big time with International Mining. His signature techniques include a penchant for companies with rocky managements and unhappy shareholders, and the quiet buying-up of shares by a "group of investors," some of whom just happen to be directors of the same holding company. But the neatest twist Murdock has added to the takeover game has been to secure well-placed allies on the board of the company he has chosen to move in on—which in the case of International Mining appears to have included the entire board.

Murdock's record has not been one of unbroken success, though even when defeated in a takeover bid, he usually has managed to make money on the deal. His worst setback was a disastrous venture into the banking business which left him with little in the way of assets but a near-bankrupt tax-loss company, Financial Corp. of Arizona, a small personal fortune, and a good credit rating with a wide range of financial institutions apparently unconcerned about his lack of success in their own line of business. That was apparently all he needed to get him started on the acquisition trail.

Murdock's business career began in 1940, when he dropped out of high school to run first a gas station and then a short-order restaurant in Detroit. After World War II, he moved out to Phoenix and entered real estate. By 1960, the Arizona development boom had turned him into a 37-year-old millionaire real estate operator controlling $25 million in funds. With friends in Phoenix, he put together Financial Corp. of Arizona, an OTC financial services outfit which controlled a bank, a savings-and-loan association, two title insurance companies and a privately owned property management and development firm, David H. Murdock Development Co.

Timing off

Murdock's timing was way off; FCA became an easy source of loans for large commercial and residential projects when Phoenix already showed signs of overbuilding. The collapse of the Arizona real estate market in 1964, and the indictment of an officer at a subsidiary for lending irregularities, led to a run on the savings and loan and massive losses. The subsidiary, Union Title Insurance, was placed in receivership in April 1965. Most of FCA's assets, including its interests in Pioneer Bank of Arizona, Home Savings & Loan, another title insurance company and real estate acquired through foreclosures on bad loans, had to be sold off over the next several years to cover its debts. By the end of 1968, FCA was a shell, its principal assets two downtown Phoenix office buildings and tax-loss credits of $4.4 million which were usable between 1969 and 1973.

Murdock shrugged off the setback (he was FCA's largest shareholder, with over 20% of the stock); he switched turf to Southern California and went back into real estate in Orange County through his private development company. He also started to hunt takeover targets which could profitably use tax-loss credits, and was joined by two new business partners: Willard D. Voit, chairman of Voit Rubber, and George B. Cook, president and chairman of Bankers Life Insurance of Lincoln, Neb.

In February 1969, Murdock and Cook obtained a $1 million short-term bank loan from the First National Bank & Trust of Lincoln, which they personally guaranteed, and another $300,000 from Voit, and bought Yankee Hill Brick Manufacturing Co. (in Lincoln) for $1.25 million from its parent, Ferguson & Co. FCA than took over both Yankee Hill and the debt, together with additional loans from Cook and Voit (who became directors), in a series of transactions in which FCA's equity was substantially diluted and Murdock was issued shares in settlement of earlier loans which increased his holdings to 32%. A small Arizona property company, Mogollon Investment Corp., also was purchased. And, in October 1969, Murdock was narrowly prevented from snapping up another modest-sized Nebraska firm, Store Kraft Manufacturing, of Beatrice.

Parallels

The raid on Store Kraft holds interesting parallels with allegations currently being made in a lawsuit in which Murdock, is involved as the result of an attempt last year to take over Amex-listed Ormand Industries. George Cook's brother, William W. Cook, head of the Beatrice National Bank & Trust Co. and a director of Store Kraft, went to work soliciting options from shareholders without the knowledge of Store Kraft's management. George Cook's son, G. Bradford Cook (who later resigned as chairman of the SEC in 1973 in the wake of the Vesco case), also was heavily involved in the buying, as eventually was Murdock. Collectively, they managed to purchase about 17% of the company's stock; Murdock and another Cook associate and FCA director even gained seats on the board. But their bid for control was finally blocked when Store Kraft President Merle Jones solicited and received offers from possible corporate buyers of $15 a share, as against the $9.50 a share Murdock's partners were offering. Murdock and his partners were finally bought out—at a tidy profit—for $15 a share.

The Cooks' Nebraska connection short-circuited, Murdock went back to California to acquire a number of small building materials companies: ceramic tile-maker Huntington Tile in 1970, a couple of Huntington distributors in 1971, a hardware company in 1972, two more Huntington distributors in 1973 and 1974. By this time, FCA had sold off the last of its Phoenix real estate, shifted its corporate offices to Los Angeles and edged back into the black. In the company's 1973 annual report, Murdock reiterated management's commitment "to a program of aggressive

Cont. on page 8B

Great Plains real estate liked by David Murdock

David Murdock has such a strong liking for Great Plains investments that his real estate portfolio in 12 neighboring states is valued at more than $100 million, according to Murdock Development Co. of Los Angeles. This includes these Lincoln properties:

The 20-story First National Bank Building.

The 340,000 square foot Ace Hardware Distribution Center.

The former Nebraska Farmer building.

Murdock has developed more than $200 million in real estate. Murdock Management Co. handles the leasing of more than three million square feet of commercial real estate, through branch operations in 14 cities, a spokeswoman said.

Back to the 'Sixties

Cont. from page 7B

but conservative external growth. Our merger/acquisition efforts resulted in the analyzing of over 150 companies during 1973." Among them: Pacific Holding Corp.

Pacific Holding consisted of companies making clay pipe, clay tile and tin cans; some minor real estate interests; and a subsidiary real estate development firm, McCarthy Co., which was a drain on both the concern's balance sheet and its income statement. But excluding McCarthy, as management plaintively pointed out in its 1973 annual, Pacific's balance sheet showed $35 million in assets and long-term debt of only $45,000.

Other notice

Those enticing numbers drew other notice as well. In the summer of 1973, a group of investors led by M.J. Coen, a former associate of financier G. Arnholt Smith, began accumulating shares in Pacific, which filed suit to block any takeover. In December, New York wheeler-dealer Arthur L.

George B. Cook

Carter was elected to the board of Pacific following the purchase of a 5% holding by his South Bay Corp.—formerly Fifth Avenue Coach Lines (Barron's, May 28, 1973). Then, in January, Murdock and the Cooks disclosed the acquisition of 19% of Pacific's 1.7 million outstanding shares, having bought out the Coen group as well.

Once again Murdock had the inside track, with two allies on the Pacific board—former McCarthy Co. President James H. McCarthy, and Pacific Vice President Rene R. Woolcott. Woolcott, who had already borrowed $75,000 from Pacific in return for an option on his own 6% holding, received an additional bank loan of $75,000 guaranteed by Murdock and his partners in return for an irrevocable proxy on the shares. Carter sold out to Murdock in time for Pacific's annual meeting in April, where the rebels took over, backed by other shareholders dissatisfied with the ousted management.

After taking over Pacific Holding as a group of private investors, Murdock and his partners turned around and moved to have FCA acquired by Pacific at a price two and a half times its then-current OTC bid. Unfortunately, there were setbacks: McCarthy's losses caused Pacific's annual dividend to be slashed from 34 cents to 16 cents a share (the price of the stock tumbled from around 7½ to around 2½); and in February 1975 plans for the FCA acquisition were terminated (temporarily), due to "prolonged delays" in obtaining SEC approval of the transaction.

The FCA merger finally went through in April 1976. By that time, Woolcoot, whose proxies had helped give Murdock control of Pacific, had defaulted on his indebtedness both to Pacific and to several bank lenders and resigned from his positions with the company. Murdock picked up both the debts and the shares, adding the latter to the bulk of his partners' holdings which he had purchased from them through unsecured bank borrowings by his private development company. Repurchases of its own common by Pacific during 1976 left Murdock by year-end with 30% of the company's 1.3 million shares (now up sharply in price to around 11½).

Unloaded

Finally, moreover, Pacific succeeded in unloading the albatross McCarthy Co. to a group led by its chairman; Pacific then used its virtually debt-free equity base (reduced, it is true, from $29.3 million to $24.6 million by the McCarthy losses of 1974 and 1975), to secure revolving credit note lines with its banks totaling $13 million—ammunition for a new acquisition campaign.

The bullets, in fact, already were flying. In August 1976, a suit was filed in federal court in Los Angeles by Ormand Industries, which has stakes in cans, outdoor advertising and services connected with oil, gas and water well drilling. The suit alleged an illegal attempt to take over Ormand was being made by a group of investors led by Pacific directors G. Bradford Cook (the former chairman of the SEC), George B. Cook, and Willard D. Voit—and claimed that the defendants had filed a "false and misleading" Schedule 13D on acquiring more than 5% of Ormand's stock, attempting to conceal that they were acting on behalf of Murdock and Pacific Holding.

Bradford Cook flatly denied that he or the other directors were acting as anything but private investors; in May of this year, he hit back with a stockholders' suit alleging waste, mismanagement and violations of securities laws by Ormand management. Just six days later, Ormand consented to the court decree in a separate action brought against it by the SEC for improper use of corporate funds and faulty accounting practices, following complaints made by two stockholders, H. P. Skoglund and Barry Ackerley, who had been supporting the Cook partnership. But Ormand's suit to block the Cook takeover bid remains before the courts.

Whether or not Murdock and Pacific were behind those "private investors," Murdock was certainly busy elsewhere. In the fall of 1976, Pacific shelled out $7 million to buy up 21.4% of the shares of International Mining, on Murdock's advice, began accumulating shares in another Big Board firm, Iowa Beef Processors, the nation's largest meat packer. Iowa Beef's stock had been depressed as a result of press articles drawing attention to its management's history of underworld associations and violent labor disputes; International Mining has since snapped up 17% of the shares purely as an investment—according to Murdock—in an undervalued company.

Eye for value

Murdock's eye for value—and his recurring ability to get the inside track—were equally apparent in February of this year, when Pacific made its bid for the rest of International Mining. Murdock's co-directors on the IM board promptly declared that they would not oppose the offer of a $20, 9% debenture for each IM share; International Chairman Lewis B. Harder commented publicly that the offer "looks like a good one." Only outraged screams from small shareholders—and an embarrassingly high bid in April by Union Oil for Molycorp, in which International held a 23% stake—upped the offer to $25 in May; by July, Pacific had acquired 73.6% of International, and is now seeking the rest.

The market expressed no the better of the deal; in June, when it became clear that Pacific's bid had succeeded, Pacific's share price shot up from around 17 ($3 or more below International's) to 28, before settling back down to around 21 ($2-$3 above International's). On a pro forma basis, of course, the budding conglomerate already has a long-term debt-to-equity ratio of better than two-to-one, but International has the earnings to cover the paper.

Less clear is what contribution the ho-hum profits of FCA's bricks and ceramic tiles, or Pacific's clay pipes and tin cans, can make to a corporate collection which now includes interests in mineral resources, a marine terminal facility and substantial investments in Iowa Beef Processors and Union Oil (which traded its shares for Molycorp's). But conglomerates, old and new, don't require much in the way of synergy. All they need is companies with undervalued shares, underleveraged equity and/or acquiescent managements. Obviously, there are still plenty of them out

Canton Company changes hands, gets private owner

By JESSE GLASGOW
Financial Editor of The Sun

The Canton Company has changed hands again and, in the process, has become privately owned for the first time in many years.

More than a decade ago Canton was acquired by International Mining Corporation, which later became a wholly owned subsidiary of Pacific Holding Corporation.

Until a few days ago, 36.4 per cent of the stock in that Los Angeles firm was held by its chairman and president, David H. Murdock. Mr. Murdock made an offer last April for the other 63.6 per cent; shareholders have approved the cash offer, and now he owns it all, Canton included.

When Mr. Murdock proposed the deal, he offered $28 a share. Two investment banking firms were called in, one by Pacific Holding, the other by Mr. Murdock, and asked to give opinions on a fair market value for each share.

They put the price at $32.50, and that is what Mr. Murdock is paying. It works out to $29 million for the 63.6 per cent he did not already own.

Pacific Holding has about 9 per cent debentures outstanding, issued to raise money for the purchase of International Mining (and Canton), which will continue to be listed on the American Stock Exchange. Its common stock has traded on both the American and Pacific exchanges.

The Canton Company was founded in 1828, by some of the same men who organized the Baltimore and Ohio Railroad the same year.

Peter Cooper, the New York industrialist who built the B. & O.'s first locomotive, was a prime mover in Canton, and he claimed in later years that his money represented the only paid in capital. He still got out with a profit.

Daniel Drew, who admitted a "fondness for Canton shares," was in and out of the stock many times as it jumped up and down in market value.

From the beginning Canton was a big holder of land suitable for development, and gradually it expanded into stevedoring, marine terminal operations, warehousing and belt-line railroad operations.

After the Depression, it was owned by Pennroad Corporation, a holding company that in 1958 became Madison Fund. The investment company sold it to International Mining in 1964, some years before International Mining became a wholly owned subsidiary of Pacific Holding.

Scott has new directors

Scott Paper Company, with a plant in Fort Edward, has announced the election of four directors, increasing the size of its board to 20 directors.

Three of those elected are officers of Brascan Limited of Toronto, Ontario. They are Peter F Bronfman, chairman; J Trevor Eyton, president and chief executive officer and Jack L Cockwell, executive vice president.

The fourth director is Lewis B Harder, chairman and president of International Mining Corporation in New York and a director of Brascan Limited.

HISTORY

"In the early 1990's, following the NSF disgorgement of commercial Internet traffic from the NSFNet, [Rodney Lance Joffe (born 1954)] launched [**Internet Media Network Incorporated**] as the Internet division of [American Computer Group [of CA/AZ]]. " Source - [HC004O][GDrive]

" In 1996 in partnership with **Bechtel Enterprises**, [**Internet Media Network Incorporated**] was renamed [Genuity Incorporated], which then went on to became one of the largest ISP Data Center Operators in the world. The company was driven by Hopscotch™, invented and patented by [Rodney Lance Joffe (born 1954)], and the very first formal content distribution and load balancing technology. " Source - [HC004O][GDrive]

"[Rodney Lance Joffe (born 1954)] remained as the Chief Technical Officer of **Genuity** until the end of 1997 when [Genuity Incorporated] was acquired by [GTE Corporation]. He was then appointed Vice-President, Strategic Technologies, and Chief Technology Officer of the Business Services division of **GTE Internetworking**." Source - [HC004O][GDrive]

FINANCE

Financial Manager

Internet Media Network (IMN) is a Bechtel Company which sells Internet Access and other related services.

We are currently seeking an individual for our Phoenix office to oversee selected financial transactions, operations and financial reporting. Responsibilities include managing cash accounting activities, implementing commission programs with Sales/Marketing management, overseeing general accounting activities, and interfacing with outside financial institutions and internal organizations.

Candidates should have a degree in Accounting or other finance related area and experience with billings within a high-volume transaction environment. Preferred applicants will have an innovative approach to using systems for implementing solutions to business requirements and using the Internet as an operational tool. Proficiency with Excel and Excel Pivot Tables as well as excellent communication and management skills required.

For immediate consideration, please send resume to:

The T1 years

Los Nettos Regional Network – the T1 years

While most regional networks were built as 56 kilobit per second networks, Los Nettos started with T1 (1.5 megabit per second) links between all of its sites. When CERFNet was completed in 1989, it provided Los Nettos with a backup connection to the NSF Backbone and vice versa.

- 1988 – NSFNET upgraded to T1 backbone.
- 1988, June – First commitments made for funding for Los Nettos.
- 1988, October – First Cisco gear arrives at USC's Information Sciences Institute for testing and configuration.
- 1988, December – First four nodes are up and passing packets (Caltech, UCLA, ISI, USC), as the all-T1 regional network is realized.
- 1989 – Los Nettos adds nodes for RAND Corporation, Jet Propulsion Laboratory (JPL), TRW, Trusted Information Systems (TIS), IBM, UNISYS, and Naval Ocean Systems Command (NOSC), completing the orginial network.
- 1989 – Los Nettos allows associate connections via member connections.
- 1994 – Los Nettos upgrades its connection to the Internet backbone to DS3 (45Mbps).

https://www.losnettos.net/subpage-1/subpage-2/1995-2000-the-ds3-years/

1995-2000 – The DS3 years

From 1988 to 1994, T1 connections were adequate to run the network, including connections to the NSFNet. In 1994, the connection to NSFNET was upgraded to DS3. Demand for internet connectivity jumped and Los Nettos upgraded the majority of its member connections to 45 Mbps connections (DS3).

- **1995 – American Computer Group (ACG) joins Los Nettos as non-voting member.**
- 1995 – Los Nettos backbone is ugraded to 45Mbps.(T3)
- 1995 – The Associate Program is integrated into Los Nettos and expanded to include hub sites at the Information Sciences Institute, University of Southern California, Caltech, American Computer Group, Jet Propulsion Laboratory, and TRW-Space Systems.
- 1996 – Los Nettos co-founds the MAE-LA / LAAP internet exchange in downtown Los Angeles and Marina del Rey with **Metropolitan Fiber Systems (MFS).**
- 1998 – Los Nettos Co-founder Jon Postel dies on October 16; anniversary plans are delayed.
- 1999 – Los Nettos starts upgrades to gigabit backbone.
- 2000 – Los Nettos celebrates belated 10th-anniversary party in October.

History

The Los Nettos Consortium was created in 1988 by group of Southern California researchers to provide cost-effective connections to the national NSFNET backbone for local campuses and research institutes. **Led by Danny Cohen and Jon Postel of USC's Information Sciences Institute (ISI), the group included Charles Seitz of Caltech, Leonard Kleinrock of UCLA, and Richard Kaplan of USC. The group had the benefit of support from Mark Pullen of the Defense Advanced Research Projects Agency's Information Science and Technology Office (DARPA/ISTO).**

The founding members of Los Nettos made commitments to create the regional network in June 1988. The necessary hardware began to arrive in October 1988; testing started in November, and the first four nodes of the network (ISI, UCLA, USC, Caltech) were up by December 1988. **After CERFNet was built in the San Diego area in 1989, Los Nettos and CERFNet provided backup links to the NSFNET backbone for each other.**

Today, Los Nettos continues to provide connectivity to Los Angeles area educational and research organizations. It is administered and operated by the Information Technology Services (ITS) division of the University of Southern California on behalf of the Los Nettos Consortium.

Timeline

- 1988-1995 – The T1 years
- 1995-2000 – The DS3 years
- 2000-present – 10 gigabits and beyond

See the 1988 entry in the Hobbes Internet Timeline for a more general timeline.

FROM THE COVER

U.S. releases evidence in anthrax case

ANTHRAX [From Page 1A]

million payment to a man wrongly identified as a person of interest, Steven J. Hatfill, who also worked at Fort Detrick.

A memorial service was held for Ivins yesterday at Fort Detrick, where the scientist had labored

cording to an affidavit, except that "home was not good" and he went to the lab "to escape."

Ivins "engaged in behavior and made a number of statements that suggest consciousness of guilt," Taylor said, including discarding a book on DNA coding while under round-the-clock sur-

HOW THE CASE DEVELOPED

September-October 2001

- Researcher Bruce Ivins' evening use of his laboratory at the U.S. Army Medical Institute of Infectious Diseases at Fort Detrick spikes. It is used for research on dangerous animal and human pathogens, including anthrax.
- Anthrax is mailed to lawmakers on Capitol Hill and members of the news media in New York and Florida. By late November, five people are dead and 17 sickened. The victims include postal workers and others who came into contact with the anthrax.

Feb. 2002: Ivins provided anthrax to the FBI to compare with that used in the attacks; however, authorities say the samples were unusable because he failed to follow proper protocols.

April 2002: Ivins provides another anthrax sample. Through genetic testing, it is found to be negative for the presence of the four mutations found in the anthrax used in the attacks.

December 12, 2003: An FBI special agent accompanies Ivins into the laboratory and identifies additional anthrax samples of Ivins' and others that had not been submitted previously.

April 7, 2004:

- Ivins submits the newly identified samples to the FBI.
- On this afternoon, an FBI special agent accompanies Ivins into his lab and seizes other samples that had previously not been submitted, including one known as RMR-1029.

June 17, 2004: The RMR-1029 samples seized from Ivins' lab test positive in comparison with the anthrax used in the 2001 attacks. However, the samples Ivins had submitted did not show a link.

Bruce Ivins in Army photo.
HO AFP/GETTY IMAGES

March 31, 2005. Ivins is informed of the test results. Ivins indicates that he had been aware of the match and that he had told an FBI agent of it. The agent denies having the conversation.

May 7, 2007: Ivins tells investigators that, within three months after the letter attacks, he was aware that his stock of anthrax exhibited similarities to that used in the attacks. He says he learned this information from three co-workers at the lab who participated in the forensic analysis of the anthrax in the letters. Each of those three coworkers denies disclosing such information to Ivins.

for decades to develop vaccines for anthrax. The service was attended by hundreds of soldiers, scientists and family members, according to Ivins' lawyers, who released a statement saying that no concrete evidence had been presented against their client.

"The government's press conference was an orchestrated dance of carefully worded statements, heaps of innuendo and a staggering lack of real evidence — all contorted to create the illusion of guilt by Dr. Ivins," said the lawyers, Paul F. Kemp and Thomas M. DeGonia. They have repeatedly said he was innocent.

But Ivins clearly knew investigators were closing in. His house had been under surveillance for a year, federal agents followed him wherever he went and he had been interviewed by investigators several times. Ivins had a history of mental illness, but the pressure led to a further decline in his condition, colleagues have said, to the point that he was hospitalized.

On July 9, Ivins was attending a group therapy session in Frederick. According to an affidavit released yesterday, he told the group he was a suspect in the anthrax investigation and that he was angry at the government and the investigators.

"He said he was not going to face the death penalty," the affidavit said, "but instead had a plan to kill co-workers and other individuals who had wronged him. He said he had a bulletproof vest, and a list of co-workers, and added that he was going to obtain a Glock firearm from his son within the next day, because federal agents are watching him and he could not obtain a weapon on his own."

He was admitted to a psychiatric wing of Frederick Memorial Hospital the next day. Shortly after he was released, on July 24, he took the overdose of Tylenol and codeine that killed him.

Yesterday, federal lawyers asked a judge in Washington to unseal search warrants and affidavits that spelled out their case, and FBI Director Robert S. Mueller III met with families of the anthrax victims and lawmakers to lay out the evidence against Ivins. One congressman who was briefed said that the presentation was "compelling" but that he was not convinced Ivins acted alone.

According to documents released, investigators traced the anthrax to Ivins' lab in 2005 using newly developed genetic mapping techniques. They concluded that all the anthrax used in the mailings that led to fatalities came from a single flask of anthrax spores known as RMR-1029.

That flask was "created and solely maintained by Dr. Ivins," said Jeffrey Taylor, U.S. attorney for the District of Columbia. "No one received material from that flask without going through Dr. Ivins. We thoroughly investigated every other person who could have had access to the flask, and we were able to rule out all but Dr. Ivins."

The time needed for that investigation explains why Ivins was not identified as the principal suspect until two years later, in 2007, Taylor said. There was "a tremendous amount of additional investigation that needs to take place to identify the universe of individuals who have access to that flask," he said. "We're talking about a large number of individuals, over 100, who potentially had access to this substance."

Ivins' off-hours time in the lab also raised suspicions. Just before the first set of anthrax letters was mailed, on Sept. 18, 2001, Ivins spent long hours at night in the lab containing the anthrax. And then again, before the second set of letters was mailed, on Oct. 9, he spent many night hours in the lab. He was alone during that time, officials said, suggesting he had the time to convert the anthrax into the deadly form that turned up in the letters.

When investigators asked Ivins about those extended hours, he offered "no legitimate reason," according to the affidavit. He said he was working on a project to develop a new vaccine, but he refused to provide any details, the affidavit said.

Ivins' lawyers said he was cooperating with the investigation and had provided hundreds of documents to the government. He had also undergone hours of polygraph tests, they said.

"Dr. Ivins has been extensively questioned by the FBI and has undergone multiple polygraph examinations," the lawyers said. "He has consistently denied any involvement in the anthrax attacks."

Ivins was also under surveillance. And in 2002, when investigators asked Ivins to provide a set of anthrax samples from the RMR-1029 flask, he provided a different set instead.

The correct sample was not provided until 2004.

Investigators also released e-mails yesterday that they said point to Ivins' guilt. On Sept. 26, 2001, Ivins wrote, "Bin Laden terrorists for sure have anthrax ... Osama Bin Laden has just decreed death to all Jews and all Americans." One of the anthrax mailings included the statement: "WE HAVE THIS ANTHRAX ... DEATH TO AMERICA ... DEATH TO ISRAEL."

The e-mails also chronicle Ivins' mental condition. Around the time of the attacks, he wrote a number of e-mails in which he seeks to understand his mental health issues. At one point, he writes that his psychiatrist and counselor believe he has a "Paranoid Personality Disorder" and he says that he has "incredible paranoid, delusional thoughts at times."

Ivins was also troubled during that time because an anthrax vaccine project on which he was working was failing, and he believed that success of the venture was important, the federal authorities said.

"One theory is that by launching these attacks, he creates a situation, a scenario where people realize they need to have this vaccine," Taylor said yesterday.

Officials also sought to explain why the anthrax letters — sent to the offices of Sens. Patrick J. Leahy and Tom Daschle as well as NBC News, *The Washington Post* and the *Sun* tabloid in Florida — were all mailed from Princeton, N.J. Ivins had a habit of traveling long distances to mail letters to disguise the sender, officials said.

They also said he was obsessed with the Kappa Kappa Gamma sorority, and the street box in Princeton from which the letters were posted is just 60 feet from a Kappa Kappa Gamma office. Among other evidence presented in the affidavits, one of the documents quotes a posting on a Web site last year in which Ivins wrote that the sorority had "labeled me as an enemy decades ago, and I can only abide by their 'Fatwah' on me."

Furthermore, investigators determined that the pre-stamped envelopes used in the mailings were bought from a Frederick post office where Ivins had a box. He was also a prolific writer to Congress and the media. A search of his house last fall turned up 68 such letters.

Officials acknowledged lacking direct evidence to connect Ivins to the anthrax attacks but said the circumstantial evidence was overwhelming.

"We have a flask that's effectively the murder weapon from which those spores were taken that was controlled by Dr. Ivins," Taylor said. "The anthrax in that flask was created by Dr. Ivins. We have the suspicious behavior that he had undertaken over the years.

"Circumstantial evidence, sure. Some of it is," Taylor continued. "But it's compelling evidence and in our view would have helped us prove the case against Dr. Ivins beyond a reasonable doubt."

Daschle said yesterday that he would not comment until he had a chance to review the evidence released. Rep. Rush Holt, whose central New Jersey district includes Princeton, said the evidence was "compelling" after receiving a briefing from the FBI director.

But, Holt said, "a number of important questions remain unanswered, such as why investigators remained focused on Dr. Hatfill long after they had begun to suspect Dr. Ivins of the crime and why investigators are so certain that Ivins acted alone."

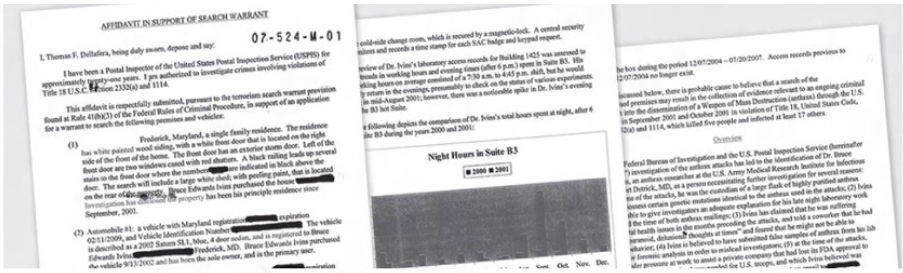
"DR. BRUCE E. IVINS WAS RESPONSIBLE FOR ... THE 2001 ANTHRAX MAILINGS."
JOSEPH PERSICHINI, FBI



AFFIDAVIT IN SUPPORT OF SEARCH WARRANT

07-524-M-01

I, Thomas F. Dellafera, being duly sworn, depose and say:

I have been a Postal Inspector of the United States Postal Inspection Service (USPIS) for approximately [redacted] years. I am authorized to investigate crimes involving violations of Title 18 U.S.C. Section 2332(a) and 1114.

This affidavit is respectfully submitted, pursuant to the terrorism search warrant provision found at Rule 41(b)(3) of the Federal Rules of Criminal Procedure, in support of an application for a warrant to search the following premises and vehicles:

(1) [redacted] Frederick, Maryland, a single family residence. The residence has white painted wood siding, with a white front door that is located on the right side of the front of the home. The front door has an exterior storm door. Left of the front door are two windows eased with red shutters. A black railing leads up several stairs to the front door where the numbers [redacted] are indicated in black above the door. The search will include a large white shed, with peeling paint, that is located on the rear of the property. [redacted] Bruce Edwards Ivins purchased the house [redacted] Investigation has determined the property has been his principle residence since September, 2001.

(3) Automobile #1: a vehicle with Maryland registration [redacted] expiration [redacted] The vehicle is described as a 2002 Saturn SL1, blue, 4 door sedan, and is registered to Bruce Edwards Ivins [redacted] Frederick, MD. Bruce Edwards Ivins purchased the vehicle 9/13/2002 and has been the sole owner, and is the primary user.

Picture - Ivins at a 2003 awards ceremony at USAMRIID

Born April 22, 1946 in Lebanon, Ohio, U.S.

Died July 29, 2008 (aged 62) at Frederick Memorial Hospital , Frederick, Maryland, U.S.

Cause of death Suicide by overdose

Education University of Cincinnati (Ph.D.)

Employer United States Army Medical Research Institute of Infectious Diseases

Bruce Edwards Ivins (/ˌ aɪvɪnz/; April 22, 1946 – July 29, 2008)[1] was an American microbiologist, vaccinologist,[1] senior biodefense researcher at the United States Army Medical Research Institute of Infectious Diseases (USAMRIID), Fort Detrick, Maryland, and the suspected perpetrator of the 2001 anthrax attacks.[2]

On July 29, 2008, he died of an overdose of acetaminophen (Tylenol) in an apparent suicide after learning that criminal charges were likely to be filed against him by the Federal Bureau of Investigation for an alleged criminal connection to the 2001 anthrax attacks.[3][4][5] No formal charges were ever filed against him for the crime, and no direct evidence of his involvement has been uncovered.[6]

At a news conference at the United States Department of Justice (DOJ) on August 6, 2008, FBI and DOJ officials formally announced that the Government had concluded that Ivins was likely solely responsible for "the deaths of five persons, and the injury of dozens of others, resulting from the mailings of several anonymous letters to members of Congress and members of the media in September and October 2001, which letters contained *Bacillus anthracis*, commonly referred to as anthrax."[7][8] On February 19, 2010, the FBI released a 92-page summary of evidence against Ivins and announced that it had concluded its investigation.[9][10] The FBI conclusions have been contested by many, including senior microbiologists, the widow of one of the victims,[11] and several prominent American politicians. Senator Patrick Leahy (D-VT) who was among the targets in the attack, Senator Chuck Grassley (R-IA), Senator Arlen Specter (R-PA), Representative Rush Holt (D-NJ), and Representative Jerrold Nadler (D-NY)[6][12][13] all argued that Ivins was not solely responsible for the attacks.

The FBI subsequently requested a panel from the National Academy of Sciences to review its scientific work on the case.[14] On May 15, 2011, the panel released its findings, which "conclude[d] that the bureau overstated the strength of genetic analysis linking the mailed anthrax to a supply kept by Bruce E. Ivins."[6][15] The committee stated that its primary finding was that "it is not possible to reach a definitive conclusion about the origins of the *B. anthracis* in the mailings based on the available scientific evidence alone."[12][13][16][17][18][19][20][21]

Early and family life

Bruce Ivins was born, and spent his youth, in Lebanon, Ohio, a small town 30 miles (48 km) northeast of Cincinnati.[22] His parents were Thomas Randall Ivins and Mary Johnson (*nee* Knight) Ivins, and he was the youngest of three brothers.[1] His father, a pharmacist, owned a drugstore and was active in the local Rotary Club and Chamber of Commerce. The family went regularly to Lebanon Presbyterian Church, although Ivins was later a Catholic parishioner.[23] According to C.W. Ivins, one of Ivins' older brothers, their mother Mary was violent and physically abusive to all three children. When she discovered she was pregnant with Bruce, a pregnancy that was unplanned and unwanted, she repeatedly tried to abort the child by throwing herself down a set of stairs. Ivins would eventually hear the story of his mother's attempt to abort him.[22]

Avidly interested in science, Ivins was an active participant in extracurricular activities in high school, including National Honor Society, science fairs, the current events club, and the scholarship team all four years. He ran on the track and cross-country teams, worked on the yearbook and school newspaper, and was in the school choir and junior and senior class plays.[23]

In December 1975, Ivins married nursing student Mary Diane Betsch (known as Diane), to whom he remained married until his death.[1][24] The couple had two children.[1][23][25]Diane Ivins was a homemaker and full time parent who also ran a daycare center out of the family's home.[26] His wife, children, and brothers were all still alive at the time of his death; his parents were deceased.[1]

Education and career

Ivins graduated with honors from the University of Cincinnati with a B.S. degree in 1968, an M.S. degree in 1971, and a Ph.D. degree in 1976, all in microbiology.[2] Ivins conducted his Ph.D. research under the supervision of Dr. Peter F. Bonventre. His dissertation focused on different aspects of toxicity in disease-causing bacteria.[23]

Ivins was a scientist for 36 years[1] and senior biodefense researcher at the United States Army Medical Research Institute of Infectious Diseases (USAMRIID) in Fort Detrick, Maryland for 18 years.[2] After conducting research on *Legionella* and cholera, in 1979, Ivins turned his attention to anthrax after the anthrax outbreak in the Soviet city of Sverdlovsk (now known as Yekaterinburg), which killed at least 105 after an accidental release at a military facility.[25]

Ivins had published at least 44 scientific papers dating back to May 18, 1969.[27][28] His earliest known published work pertained to the response of peritoneal macrophages, a type of white blood cell, to infection by *Chlamydia psittaci*, an infectious bacterium that can be transmitted from animals to humans.[29][30] He was the co-author of numerous anthrax studies, including one on a treatment for inhalational anthrax published in the July 7, 2008 issue of the journal *Antimicrobial Agents and Chemotherapy*.[5] He often cited the 2001 anthrax attacks in his papers to bolster the significance of his research in years subsequent to the attacks.[31] In a 2006 paper published in the prestigious journal *Proceedings of the National Academy of Sciences*, he wrote with his co-authors

Shortening the duration of antibiotic postexposure prophylaxis in a bioterrorism event involving *B. anthracis* by adding postexposure vaccination could greatly alleviate problems of noncompliance and side effects associated with prolonged antibiotic therapy. The value of adding vaccination to postexposure antibiotic prophylaxis should be considered in planning the public health response to bioterrorism events involving inhalational anthrax.[31]

antibiotic prophylaxis should be considered in planning the public health response to bioterrorism events involving inhalational anthrax.[31]

Ivins was a co-inventor on two United States patents for anthrax vaccine technology, U.S. Patent 6,316,006 and U.S. Patent 6,387,665. Both of these patents are owned by his employer at the time, the United States Army.

On March 14, 2003, Ivins and two of his colleagues at USAMRIID at Fort Detrick received the Decoration for Exceptional Civilian Service — the highest award given to Defense Department civilian employees — for helping solve technical problems in the manufacture of anthrax vaccines.[32]

Alleged involvement in 2001 anthrax attacks and investigations

The 2001 anthrax attacks involved the mailing of several letters proclaiming "Death to America ... Death to Israel ... Allah is Great",[33] and contaminated with anthrax, to the offices of U.S. Senators Tom Daschle and Patrick Leahy, as well as to the offices of ABC News, CBS News, NBC News, the *New York Post*, and the *National Enquirer*.[34][35]

Initial investigative role

Ivins became involved in the investigation of the 2001 anthrax attacks because he was regarded as a skilled microbiologist.[2] Starting in mid-October, Ivins and his colleagues worked long hours testing samples to distinguish real anthrax letters from the numerous hoaxes that were sent out at this time.[36] Ivins also helped the FBI analyze the powdery material recovered from one of the anthrax-tainted envelopes sent to a U.S. senator's office in Washington, D.C.[2]

Results of the investigation were initially distributed to the public via ABC News, claiming "four well placed sources" had confirmed that "trace amounts of the chemical additives bentonite" were found in the anthrax samples, and that this was the chemical signature of Iraqi-made anthrax.[33] However, it was later confirmed that no bentonite was ever found in the anthrax samples.[33] While it is presumed that Ivins was one of ABC News' four sources, ABC News refused to reveal their identities, which has contributed to a mystery surrounding Ivins' role in the initial investigation and its widely reported findings.[33]

2002 Fort Detrick anthrax containment breach

In 2002, an investigation was carried out as a result of an incident at Fort Detrick where anthrax spores had escaped carefully guarded rooms into the building's unprotected areas.[37] The incident called into question the ability of USAMRIID to keep its deadly agents within laboratory walls seven months after the anthrax mailings.

A coworker reportedly told Ivins that she was concerned she was exposed to anthrax spores when handling an anthrax-contaminated letter. Ivins tested the technician's desk area that December and found growth that had the earmarks of anthrax. He decontaminated her desk, computer, keypad and monitor, but did not notify his superiors.[37]

2008 investigation

For six years, the FBI focused its investigation on Steven Hatfill, considering him to be the chief suspect in the attacks. In March 2008, however, authorities exonerated Hatfill and settled a lawsuit he initiated for $5.8 million.[38] According to ABC News, some in the FBI considered Ivins a suspect as early as 2002.[39] FBI Director Robert Muellerchanged leadership of the investigation in late 2006, and at that time Ivins became the main focus of the investigation.[2]

After Hatfill was no longer considered a suspect, Ivins began "showing signs of serious strain".[40] As a result of his changed behavior, he lost access to sensitive areas at his job. He began being treated for depression and expressed some suicidal thoughts.[2] On March 19, 2008, police were summoned[*by whom?*] to Ivins' home in Frederick, where they found him unconscious and sent him to the hospital.[23]

In June 2008, Ivins was involuntarily committed to a psychiatric hospital. The FBI said that during a June 5 group therapy session there, Ivins had a conversation with a witness, during which he made a series of statements about the anthrax mailings that the FBI said could best be characterized as "non-denial denials".[41] When asked about the anthrax attacks and whether he could have had anything to do with them, the FBI said that Ivins admitted he suffered from loss of memory, stating that he would wake up dressed and wonder if he had gone out during the night. His responses allegedly included the following:

"I can tell you I don't have it in my heart to kill anybody"

"I do not have any recollection of ever have doing anything like that. As a matter of fact, I don't have no clue how to, how to make a bio-weapon and I don't want to know."

"I can tell you, I am not a killer at heart"

"If I found out I was involved in some way, and, and ..."

"I don't think of myself as a vicious, a, a nasty evil person."

"I don't like to hurt people, accidentally, in, in any way. And [several scientists at USAMRIID] wouldn't do that. And I, in my right mind wouldn't do it [laughs] ... But it's still, but I still feel responsibility because it [the anthrax] wasn't locked up at the time ..."

Late in July 2008, investigators informed Ivins of his impending prosecution for alleged involvement in the 2001 anthrax attacks that Ivins himself had previously assisted authorities in investigating. It was reported that the death penalty would have been sought in the case.[42] Ivins maintained his security clearance until July 10; he had been publicly critical of the laboratory's security procedures for several years.[43]

W. Russell Byrne, a colleague who worked in the bacteriology division of the Fort Detrick research facility, said FBI agents "hounded" Ivins by twice raiding his home and that Ivins had been hospitalized for depression earlier in the month.[44] According to Byrne and local police, Ivins had been removed from his workplace out of fears that he might harm himself or others. "I think he was just psychologically exhausted by the whole process", Byrne said.[45] "There are people who you just know are ticking bombs", Byrne said. "He was not one of them."[46] However, Tom Ivins, who last spoke to his brother in 1985, said, "It makes sense ... he considered himself like a god."[45]

The *Los Angeles Times* asserted that Ivins stood to profit from the attacks because he was a co-inventor on two patents for a genetically-engineered anthrax vaccine. San Francisco-area biotechnology company [**VaxGen, Incorporated**] licensed the vaccine and won a federal contract valued at $877.5 million to provide the vaccine under the Project Bioshield Act.[47] However, biological warfare and anthrax vaccine expert Meryl Nass expressed skepticism about this purported motive, pointing out that "Historically, government employees do not receive these royalties: the government does."[48]

On August 6, 2008, US Attorney Jeffrey A. Taylor, officially made a statement that Ivins was the "sole culprit" in the 2001 anthrax attacks.[49] Taylor stated

that Ivins had submitted false anthrax evidence to throw investigators off of his trail, was unable to adequately explain his late laboratory working hours around the time of the attacks, tried to frame his co-workers, had immunized himself against anthrax in early September 2001, was one of more than 100 people with access to the same strain of anthrax used in the killings, and had used similar language in an email to that in one of the anthrax mailings.[50] Ivins was also reportedly upset that the anthrax vaccine that he had spent years helping develop was being pulled from the market.[51]

Death

On the morning of July 27, 2008, Ivins was found unconscious at his home. He was taken to Frederick Memorial Hospital and died on July 29 from what was then called an overdose of Tylenol with codeine,[5][52] an apparent suicide. No autopsy was ordered following his death because, according to an officer in the local police department, the state medical examiner 'determined that an autopsy wouldn't be necessary' based on laboratory test results of blood taken from the body.[53] A summary of the police report of his death, released in 2009, lists the cause of death as liver and kidney failure, citing his purchase of two bottles of Tylenol PM (containing diphenhydramine), contradicting earlier reports of Tylenol with codeine.[54] His family declined to put him on the liver transplant list, and he was removed from life support.[54]

Immediately after news of his death, the FBI refused to comment on the situation.[5] Ivins' attorney released a statement asserting that Ivins had co-operated with the six-year investigation by the FBI and asserting that Ivins was innocent in the deaths.[55]

Anthrax investigation, post-death

Criticism of the official findings

Paul Kemp, Ivins' attorney, stated that the government's case against Ivins was "not convincing". Department of Justice official Dean Boyd stated that Ivins mailed anthrax to NBC in retaliation for an investigation of Ivins' laboratory's work on anthrax conducted by Gary Matsumoto, a former NBC news journalist. At the time, however, Matsumoto was working for ABC, not NBC. Also, Ivins passed a lie detector test in which he was questioned about his possible participation in the anthrax attacks. Boyd responded by saying that the FBI now believes that Ivins used countermeasures to deceive the polygraph examiners. "There are clearly a lot of unanswered questions," said Senator Chuck Grassley, who called for a congressional investigation into the allegations that Ivins was the anthrax killer.[56]

Those who argue for Ivins' innocence claim that the anthrax used in the attacks was too sophisticated to be produced by a lone researcher without relevant training. "In my opinion, there are maybe four or five people in the whole country who might be able to make this stuff, and I'm one of them," said Richard O. Spertzel, former deputy commander of USAMRIID.[57] "And even with a good lab and staff to help run it, it might take me a year to come up with a product as good."[57] The spores in the Daschle letter were 1.5 to 3 micrometres across, many times smaller than the finest known grade of anthrax produced by either the U.S. or Soviet bioweapons programs.[57] An electron microscope, which costs hundreds of thousands of dollars, would be needed to verify that the target spore size had been consistently achieved.[57] The presence of the anti-clumping additive silicon in the anthrax samples also suggests a high degree of sophistication as specialists working at Lawrence Livermore National Laboratory were unable to duplicate this property despite 56 attempts.[58]

While not outright rejecting the theory of Ivins' involvement, Senator Leahy asserted that "if he is the one who sent the letter, I do not believe in any way, shape or manner that he is the only person involved in this attack on Congress and the American people. I do not believe that at all."[59]

Allegations of mental illness

On August 6, 2008, the FBI released a collection of emails written by Ivins.[60] In some, Ivins describes episodes of anxiety, paranoia, and depression for which he was medicated;[61] these are referenced in the summary of the case against Ivins. A psychiatrist engaged by *The New York Times* to analyze the released documents found evidence of psychoses, but could not rule out the possibility that Ivins was feigning or exaggerating mental illness for purposes of attention or sympathy.[62]

A United States government investigative panel, called the Expert Behavioral Analysis Panel, issued a report in March 2011 which detailed more of Ivins' mental health issues. According to the panel's report, the Army did not examine Ivins' background adequately before clearing him to work with anthrax: such clearance should not have been given. The report endorses the government's implication of Ivins: circumstantial evidence from Ivins' psychiatric history supported the conclusion that Ivins was the anthrax killer.[63][64][65]

Allegations by Ivins' counselor

One of the most contested elements of the Ivins case involves the testimony of his former therapist, social worker Jean C. Duley. Documents show that Ivins was ordered late in July 2008 to stay away from Duley.[66] In her handwritten application for a protective order, Duley wrote that Ivins had stalked and threatened to kill her and had a long history of homicidal threats.[23] However, in her testimony, Duley also stated that she had only known Ivins for six months.[67]

Duley had been set to give testimony against Ivins on August 1, 2008.[45] Ivins, however, had no criminal record, whereas Duley had a history of convictions for driving under the influence and charges of battery of her ex-husband.[68] The charges forced her to quit her job, and attorney costs used up her savings, according to her fiance.[68] In a 1999 newspaper interview, Duley described herself as a former motorcycle gang member and drug user: "Heroin. Cocaine. PCP. You name it, I did it."[69] According to an article originally appearing in the *Frederick News-Post* on August 12, 2009, Duley was under house arrest when she tape recorded Ivins' allegedly "threatening" messages.[70] The *Frederick News-Post* also made available a recording of the allegedly threatening calls.[71] The nature of the audio recordings was characterized in the published report as "No threats are made or implied in the messages. More the sad ramblings of a broken man who felt betrayed."[70]

In her July 2008 restraining order Duley alleged that Ivins "has a history dating to his graduate days of homicidal threats, actions, plans, threats & actions towards theripist" [sic]. According to Duley, "Dr. David Irwin his psychiatrist called him homicidal, sociopathic with clear intentions" [sic] and she would "tetisfy with other details" [sic].[72] She further alleged a "detailed homicidal plan" to kill his co-workers after learning he was going to be indicted on capital murder charges and stated that, upon hearing of his possible indictment, Ivins had purchased a gun and a bulletproof vest.[73] Ivins was subsequently committed for psychiatric evaluation, and his home was raided by federal agents who confiscated ammunition and a bulletproof vest.[74] He was released from his committal on July 24, five days before his death.

Statement by Henry S. Heine

Henry S. Heine, a microbiologist who was Ivins' fellow researcher at the Army Medical Research Institute, told a National Academy of Sciences panel on April 22, 2010, that he considered it impossible that Ivins could have produced the anthrax used in the attacks without detection.[14]

Heine told the 16-member National Academy of Sciences panel that producing the quantity of spores in the letters would have taken at least a year of intensive work using the equipment at the U.S. Army laboratory. Such an effort would not have escaped colleagues' notice, and laboratory technicians who worked closely with Dr. Ivins have told him they saw no such work.[14]

Heine also disputed the notion that biological containment measures where Ivins worked were inadequate to prevent the spores from floating out of the laboratory into animal cages and offices. He told the panel that if the containment was inadequate, "You'd have had dead animals or dead people".[14]

Heine said he did not dispute that there was a genetic link between the spores in the letters and the anthrax in Ivins' flask, which led the FBI to conclude that Ivins had grown the spores from a sample taken from the flask. Heine pointed out that samples from the flask were widely shared. Accusing Ivins of the attacks, he said, was like tracing a murder to the clerk at the sporting goods shop who sold the bullets.[14]

Asked by reporters after his testimony whether he believed there was any chance that Ivins had carried out the attacks, Heine replied, "Absolutely not." At the Army's biodefense laboratory, he said, "among the senior scientists, no one believes it."[14]

National Academy of Sciences scientific evidence review

The FBI asked the National Academy of Sciences to review the FBI's scientific work on the case. A panel was created, chaired by Alice P. Gast, president of Lehigh University.[14] On May 15, 2011, the panel released its findings, which "conclude[d] that the bureau overstated the strength of genetic analysis linking the mailed anthrax to a supply kept by Bruce E. Ivins."[6]

Calls for further investigation

Following the release of a National Academy of Sciences report in February 2011, Congressman Rush D. Holt, Jr. (D-NJ), a physicist from whose district the anthrax letters were mailed, re-introduced legislation "to create a 9/11-style Commission, complete with subpoena power, with a mandate to review the entire matter."[6] Senator Chuck Grassley of Iowa told *The Washington Post*: "There are no more excuses for avoiding an independent review."[6] Journalist Glenn Greenwald, who was vocal in his criticism of the anthrax investigation,[68][75][76][77][78] argued that "[o]ther than a desire to avoid finding out who the culprit was (or to avoid having the FBI's case against Ivins subjected to scrutiny), there's no rational reason to oppose an independent investigation into this matter."[6]

Interests and beliefs

Personal life

Ivins was a Roman Catholic. The *Frederick News-Post* made public several letters to the editor written by Ivins dealing with his religious views.[79] These were cited in the Department of Justice summary of the case against Ivins as suggesting that he may have harbored a grudge against pro-choice Catholic senators Daschle and Leahy, recipients of anthrax mailings.[61] In a letter, Ivins stated, "By blood and faith, Jews are God's chosen, and have no need for 'dialogue' with any gentile."[80] Ivins praised a rabbifor refusing a dialogue with a Muslim cleric.[80]

His pastimes included playing keyboard at his local church, Saint John the Evangelist;[1] he was a member of the American Red Cross;[1] he was an avid juggler and founder of the Frederick Jugglers.[23] He played keyboards in a Celtic band and would often compose and play songs for coworkers who were moving to new jobs.[23][25]

Kappa Kappa Gamma sorority and Wikipedia editing

Wikinews has related news:***Alleged Anthrax killer Bruce Ivins reportedly made edits to Wikipedia***

Ivins was reportedly obsessed with the college sorority Kappa Kappa Gamma (KKG) ever since he was rebuffed by a woman in the sorority during his days as a student at the University of Cincinnati.[81][82] According to *The Smoking Gun*, U.S. government court documents stated that Ivins edited the KKG article on Wikipedia using the account name "Jimmyflathead", by which he made a number of edits that put derogatory information about the sorority into the article and engaged in some disputes and discussions[83][84] about the content of the article.[84][85]

The FBI claims, because anthrax spores were found in a postal drop box located 300 feet (91 m) away from Princeton University's Kappa Kappa Gamma storage facility (where the Sorority keeps rush paraphernalia, initiation robes and other materials), that the anthrax laced letters had been mailed from that drop box.[86] However, no evidence was found to place Ivins in Princeton, New Jersey, on the day the letters were mailed.[81] Katherine Breckinridge Graham, an advisor to Kappa's Princeton chapter, stated that there was nothing to indicate that any of the sorority members had anything to do with Ivins.[82] Officials claim that the sorority link helps explain why the letters were mailed from Princeton, 200 miles (320 km) from the Fort Detrick laboratory in Frederick, Maryland, where Ivins worked and where it is claimed the anthrax was produced.

A United States government investigative panel, called the Expert Behavioral Analysis Panel, issued a report in March 2011 which detailed more of Ivins' obsession with the sorority. According to the panel's report, Ivins tormented a sorority member at the University of North Carolina named Nancy Haigwood. Ivins stole her notebook, which documented her research for her doctoral studies, and vandalized her residence.[63]

Biography

In 2011, journalist David Willman's book on Ivins, *The Mirage Man: Bruce Ivins, the Anthrax Attacks, and America's Rush to War*, was published. The book details Ivins' troubled history and mental problems.[87]

World War II

Henry Martin "Scoop" Jackson (May 31, 1912 – September 1, 1983) was an American politician who served as a U.S. Representative (1941–1953) and U.S. Senator (1953–1983) from the state of Washington. A Cold War liberal and anti-Communist Democrat, Jackson supported higher military spending and a hard line against the Soviet Union, while also supporting social welfare programs, civil rights, and labor unions.[1]

Born in Everett, Washington, to Norwegian immigrants, Jackson practiced law in Everett after graduating from the University of Washington School of Law. He won election to Congress in 1940 and joined the Senate in 1953 after defeating incumbent Republican Senator Harry P. Cain. Jackson supported the major civil rights of the 1960s and authored the National Environmental Policy Act, which helped establish the principle of publicly analyzing environmental impacts. He co-sponsored the Jackson–Vanik amendment, which denied normal trade relations to countries with restrictive emigration policies.

Jackson served as Chairman of the Senate Committee on Energy and Natural Resources from 1963 to 1981. He was twice an unsuccessful candidate for the Democratic presidential nomination, in 1972 and 1976. While still serving in the Senate, Jackson died in 1983.

His political beliefs were characterized by support of civil rights, human rights, and safeguarding the environment, but with an equally strong commitment to oppose totalitarianism in general, and communism in particular.[2] The political philosophies and positions of Scoop Jackson have been cited as an influence on a number of key figures associated with neoconservatism, including Paul Wolfowitz and Richard Perle, both of whom previously served as aides to the Senator.[1] The Seattle-based Henry M. Jackson Foundation was created in 1983 by his former colleagues and staff as well as his widow and other family members to further his work. In 1987, the Department of Defense gave to the Jackson Foundation a one-time, $10 million appropriation for its endowment in honor of the Senator. To date the Foundation has awarded over $26 million in grants to educational and nonprofit institutions.

Early life

Jackson was born in the home of his parents, Marine (Anderson) and Peter Jackson, in Everett, Washington on May 31, 1912. His mother and father were both immigrants from Norway.[3] Peter Jackson was born Peter Gresseth, and changed his name when he immigrated. He met Marine at the Lutheran church in Everett, where they were married in 1897. Henry was the fifth and youngest of the Jackson children; he was nicknamed "Scoop" by his sister in his childhood after a comic strip character that he was said to have resembled.

He went on to graduate with a B.A. degree from Stanford University and a J.D. degree from the University of Washington School of Law, where he joined the Delta Chi fraternity.

Early career

In 1935, the year of his law school graduation, he was admitted to the bar and began to practice law in Everett. He found immediate success and was elected to become the prosecuting attorney for Snohomish County from 1938 to 1940, where he made a name for himself prosecuting bootleggers and gamblers.

In 1961, Jackson, called by *Time* the Senate's "most eligible bachelor,"[4] married Helen Hardin, a 28-year-old Senate receptionist, but Jackson did not move out of his childhood home, where he lived with his unmarried sisters for several years. The Jacksons had two children, Anna Marie Laurence and Peter Jackson. Peter went on to serve as a speechwriter for Governor Christine Gregoire.

In Congress

Jackson successfully ran for Congress as a Democrat in 1940 and took his seat in the House of Representatives with the 77th Congress on January 3, 1941. From then on, Jackson did not lose any congressional elections.

Jackson joined the Army when the United States entered World War II but left when Franklin D. Roosevelt ordered all representatives to return home or resign their seats. He visited the Buchenwald concentration camp a few days after its liberation in 1945. He attended the International Maritime Conference in Copenhagen, Denmark, in 1945 with the American delegation, and he was elected president of the same conference in 1946, when it was held in Seattle. From 1945 to 1947, Jackson was also the chairman of the Committee on Indian Affairs.

In the 1952 election, Jackson relinquished his seat in the House for a run for one of Washington's Senate seats. Jackson soundly defeated Republican Senator Harry P. Cain and remained a senator for over thirty years. He was Washington's first U.S. Senator to be born in the state. Jackson died in office in 1983 after winning re-election for the fifth time in 1982.

Though Jackson opposed the excesses of Joe McCarthy, who had traveled to Washington state to campaign against him, he also criticized Dwight Eisenhower for not spending enough on national defense. Jackson called for more inter-continental ballistic missiles in the national arsenal, and his support for nuclear weapons resulted in a primary challenge from the left in 1958, when he handily defeated Seattle peace activist Alice Franklin Bryant before winning re-election with 67 percent of the vote, which he topped the next four times he ran for re-election.[1][5]

During the 1960 Democratic presidential primary, Jackson was the first choice of fellow Senator John F. Kennedy for a running mate, though JFK became convinced that a Southerner would better balance the ticket.[6] Lyndon B. Johnson was later selected.

Jackson boasted one of the strongest records on civil rights during the civil rights movement.[7][8] He supported the 1957 and the 1964 Civil Rights Acts.

On July 22, 1965, President Lyndon B. Johnson signed the Water Resources Planning Act into law, noting Jackson as one of the Congress members to "have made a very invaluable and very farsighted contribution to America's future."[9]

In April 1968, responding to the assassination of Martin Luther King Jr., Jackson gave a speech about the legacy and injustice of inequality.[10]

In 1963, Jackson was made chairman of the Committee on Interior and Insular Affairs, which became the Committee on Energy and Natural Resources in 1977, a position he held until 1981. In the 1970s, Jackson joined with fellow senators Ernest Hollings and Edward Kennedy in a press conference to oppose President Gerald Ford's request for Congress to end Richard Nixon's price controls on domestic oil, which had provoked oil companies into withholding gasoline during the 1973 Oil Crisis.[11][12]

Kaufman writes that after 1968, Jackson "emerged as an intellectual and political leader in the perennial struggle of U.S. foreign policy to reconcile ideals with self-interest."[6]

Jackson authored the National Environmental Policy Act, which has been called one of the most influential environmental laws in history. It helped to stimulate similar laws and the principle of publicly analyzed environmental impact in other states and in much of the world.[13] Jackson was also a leader of the fight for statehood for Alaska and Hawaii. In 1974, Jackson sponsored the Jackson-Vanik amendment in the Senate (with Charles Vanik sponsoring it in the House), which denied normal trade relations to certain countries with non-market economies that restricted the freedom of emigration. The amendment was intended to help refugees, particularly minorities, specifically Jews, to emigrate from the Soviet Bloc. Jackson and his assistant, Richard Perle, also lobbied personally for some people who were affected by this law such as Anatoly (now Natan) Sharansky.

In March 1975, Jackson released a statement in which he expressed the view that it was paramount the Franklin Peroff case be found out to be either "an aberration or was symptomatic of much greater problem" within the Drug Enforcement Administration.[14]

In June 1975, Jackson stated that if accounts about the conduct of former director of the Drug Enforcement Agency John R. Bartels Jr. were correct then his actions amounted to obstruction of justice and that evidence disclosed "in the last two days would indicate that there was a conscious, premeditated plan involving misconduct at the highest levels of the D.E.A."[15]

In July 1977, the Senate approved a funding for the experimental nuclear reactor compromise proposal by Jackson and Idaho Senator Frank Church. While the initial version by President Carter sought a decrease in funding from 150 million to 33 million, the Jackson and Church measure halved the funding to 75 million.[16]

In October 1979, the Senate voted in favor of President Carter's energy mobilization board plan, Jackson labeling the plan the "centerpiece" of Carter's program that was essential to guaranteeing the effectiveness of the rest of the legislation and was noted for successfully persuading colleagues to reject amendments to the plan.[17] Later that month, after the Senate Energy and Natural Resources Committee voted in favor of the Alaska public lands legislation, President Jimmy Carter issued a statement thanking Jackson and other members for supporting the legislation.[18]

President Jimmy Carter with Jackson

Jackson also led the opposition within the Democratic Party against the SALT II treaty and was one of the leading proponents of increased foreign aid to Israel.

For decades, Democrats who support a strong international presence for the United States have been called "Scoop Jackson Democrats," and the term is still used to describe contemporary Democrats such as Joe Lieberman and R. James Woolsey, Jr.[19][20]

Jackson served for all but the last three years of his Senate tenure with Democratic colleague and friend Warren G. Magnuson. As a result, he spent 28 years as the state's junior Senator, even though he had more seniority than all but a few of his colleagues. "Scoop" and "Maggie," as they affectionately called each other, gave Washington clout in national politics well beyond its population. They were one of the most effective delegations in the history of the Senate in terms of "bringing home the bacon" for their home state. Washington received nearly a sixth of public works appropriations but ranked only 23rd in population.[21]

Criticism

Jackson was known as a hawkish Democrat. He was often criticized for his support for the Vietnam War and his close ties to the defense industries of his state. His proposal of Fort Lawton as a site for an anti-ballistic missile system was strongly opposed by local residents, and Jackson was forced to modify his position on the location of the site several times, but continued to support ABM development. American Indian rights activists who protested Jackson's plan to give Fort Lawton to Seattle, instead of returning it to local tribes, staged a sit-in. In the eventual compromise, most of Fort Lawton became Discovery Park, with 20 acres (8.1 ha) leased to United Indians of All Tribes, who opened the Daybreak Star Cultural Center there in 1977.

Opponents derided him as "the Senator from Boeing"[22] and a "whore for Boeing"[23] because of his consistent support for additional military spending on weapons systems and accusations of wrongful contributions from the company; in 1965, 80% of Boeing's contracts were military.[1][21] Jackson and Magnuson's campaigning for an expensive government supersonic transport plane project eventually failed.

After his death, critics pointed to Jackson's support for Japanese American internment camps during World War II as a reason to protest the placement of his bust at the University of Washington.[24] Jackson was both an enthusiastic defender of the evacuation and a staunch proponent of the campaign to keep the Japanese-Americans from returning to the Pacific Coast after the war.[25]

Presidential campaigns

Jackson not only was successful as a politician in Washington state but also found recognition on the national level, rising to the position of chairman of the Democratic National Committee in 1960 after he was considered for the vice presidential ticket spot that eventually went to fellow Senator Lyndon Johnson.

Jackson ran for president twice, and both campaigns were noted for the hostile reception they received from the left wing of the Democratic Party. Jackson's one-on-one campaigning skills, which were so successful in Washington state, did not translate as well to the national stage. Even his supporters admitted that he suffered from a certain lack of charisma.[1][26][27]

1972 presidential campaign

Jackson was little known nationally when he first ran in 1972. George McGovern, who eventually won the nomination, even accused Jackson of racism for his opposition to busing despite Jackson's longstanding record on civil rights issues. Jackson's high point in the campaign was a distant third in the early Florida primary, but he failed to stand out of the pack of better-known rivals, and he made real news only later in the campaign, as part of the "Stop McGovern" coalition, which raised what would be known as the "Acid, Amnesty and Abortion" questions about McGovern. Jackson suspended active campaigning in May after a weak showing in the Ohio primary and finishing well behind McGovern, Ed Muskie, George Wallace, and Hubert Humphrey in early primaries.

Jackson re-emerged at the August Democratic convention after the runner-up, Humphrey, dropped out of the race. Jackson's name was placed in nomination by Georgia Governor Jimmy Carter, and he finished second in the delegate roll call, well behind nominee McGovern.[27][28]

1976 presidential campaign

Jackson raised his national profile by speaking out on Soviet-U.S. relations and Middle East policy regularly, and he was considered a front-runner for the nomination when he announced the start of his campaign in February 1975. Jackson received substantial financial support from Jewish-Americans who admired his pro-Israel views, but his support of the Vietnam War resulted in hostility from the left wing of the Democratic Party.

Jackson chose to run on social issues, emphasizing law and order and his opposition to busing. He was hoping for support from labor, but the possibility that Hubert Humphrey might enter the race caused unions to offer only lukewarm support.[1][26][27][29]

Jackson made the fateful decision not to compete in the early Iowa caucus and New Hampshire primary, which Jimmy Carter won after liberals split their votes among four other candidates. Though Jackson won the Massachusetts and New York primaries, he dropped out on May 1 after losing the critical Pennsylvania primary to Carter by 12% and running out of money.[1][26][27][29]

Death

Jackson's home on Grand Avenue in Everett

On September 1, 1983, Jackson died suddenly in Everett of an aortic aneurysm at the age of 71, shortly after giving a news conference condemning the

Soviet attack on Korean Air Lines Flight 007. News reports showed video footage in which he was seen reflexively massaging the left side of his chest while talking, and speculated that it was his reaction to an early symptom of the fatal attack.

Jackson's death was greatly mourned. New York Senator Daniel Patrick Moynihan stated "Henry Jackson is proof of the old belief in the Judaic tradition that at any moment in history goodness in the world is preserved by the deeds of 36 just men who do not know that this is the role the Lord has given them. Henry Jackson was one of those men." Jackson is buried in Evergreen Cemetery in Everett.

Legacy

- Jackson was posthumously awarded the Presidential Medal of Freedom in 1984. Ronald Reagan called him "one of the greatest lawmakers of our century,"[30] and stated:

  > Scoop Jackson was convinced that there's no place for partisanship in foreign and defense policy. He used to say, 'In matters of national security, the best politics is no politics.' His sense of bipartisanship was not only natural and complete; it was courageous. He wanted to be President, but I think he must have known that his outspoken ideas on the security of the Nation would deprive him of the chance to be his party's nominee in 1972 and '76. Still, he would not cut his convictions to fit the prevailing style. I'm deeply proud, as he would have been, to have Jackson Democrats serve in my administration. I'm proud that some of them have found a home here.

- In 1983, Jackson was awarded Delta Chi of the Year.
- One of Jackson's last acts as Senator was to sponsor legislation creating what became the Henry M. Jackson Foundation for the Advancement of Military Medicine, which was named after him after his death.
- Jackson's extended community of staff, colleagues and family members created the Henry M. Jackson Foundation from public monies and private donations to give grants to nonprofits and educational institutions. Its board members have included Richard Perle, Tom Foley, and Jeane Kirkpatrick.[31][32]
- On March 28, 1981, Jackson gave the principal address at the christening of the USS *Bremerton* (SSN 698). The *Bremerton* was the second ship to have the name, preceded by the USS *Bremerton* (CA 130). It was christened by Mrs. Henry M. Jackson on July 22, 1978. The USS *Bremerton* (SSN 698) was mentioned in the classic Tom Clancy novel, *The Hunt for Red October*.
- The University of Washington has named the Jackson School of International Studies in his honor. However, students objecting to Jackson's hawkish views on the Cold War in the mid-1980s caused the university to move a bust of the senator to the end of an abandoned corridor until it was restored to a more prominent place outside the Jackson School in 2006.[24]
- The U.S. Navy *Ohio*-class ballistic missile submarine *Henry M. Jackson* was also named after him, in recognition of his longtime support of the nation's military. It is the only Ohio-class submarine not named after a U.S. state.
- In 1983, the Snohomish County Public Utility District began operation of the Henry M. Jackson Hydroelectric Project outside Sultan, Washington.
- In 1994, the Everett School District completed construction of Henry M. Jackson High School in Mill Creek, Washington.
- The Henry M. Jackson Wilderness Area was created in his honor by the 1984 Washington Wilderness Act.
- **The Jewish Institute for National Security Affairs, with the cooperation of the Jackson family, awards a Henry M. "Scoop" Jackson Distinguished Service Award to individuals for their career dedication to U.S. national security. Jackson won the first award in 1982, and it was named after him after his death. Winners include Max Cleland, Joe Lieberman, Dick Cheney, Jane Harman, and Paul Wolfowitz.**[33]

Influence on neoconservatism

Jackson believed that evil should be confronted with power.[32] His support for civil rights and equality at home,[24] married to his opposition to *détente*,[32] his support for human rights[34] and democratic allies,[35] and his firm belief that the United States could be a force for good in the world[36] inspired a legion of loyal aides who went on to propound Jackson's philosophy as part of neoconservatism. **In addition to Richard Perle, neoconservatives Paul Wolfowitz, Bill Kristol, Charles Horner, and Douglas Feith were former Democratic aides to Jackson who, disillusioned with the Carter administration, supported Ronald Reagan and joined his administration in 1981,** later becoming prominent foreign policy makers in the 21st-century Bush administration. Neoconservative Ben Wattenberg was a prominent political aide to Jackson's 1972 and 1976 presidential campaigns. Wolfowitz has called himself a "Scoop Jackson Republican" on multiple occasions.[34][37] Many journalists and scholars across the political spectrum have noted links between Senator Jackson and modern neoconservatism.[1][32][35][38][39][40][41][42][43][44]

Jackson's influence on foreign policy has been cited as foundational to the George W. Bush administration's foreign policy, and the Iraq War.[45] Jackson biographer Robert Kaufman says "There is no question in my mind that the people who supported Iraq are supporting Henry Jackson's instincts."[32]

Peter Beinart, author of *The Good Fight: Why Liberals—and Only Liberals—Can Win the War on Terror and Make America Great Again*, argues that the Democratic Party should return to Jackson's values in its foreign policy, criticizing current-day neoconservatives for failing to adopt Jackson's domestic policy views along with his foreign policy views.[36][39]

The Henry Jackson Society

In 2005, the Henry Jackson Society was formed at the University of Cambridge, England. The non-partisan British group is dedicated to "pursuit of a robust foreign policy ... based on clear universal principles such as the global promotion of the rule of law, liberal democracy, civil rights, environmental responsibility and the market economy" as part of "Henry Jackson's legacy."[46] The organisation is now based in London and hosts high-profile speaker events in the House of Commons.

Jackson Papers controversy

Senator Jackson's documents were donated to the University of Washington shortly after his death in 1983, and have been archived there ever since.[47] When the materials were donated in 1983, university staff removed all information considered classified at the time.[48] Additional materials were added to the collection until 1995.[47]

At some point, library staff discovered a classified document in the collection and sent it to the government for declassification.[49] In response, in the summer of 2004, a man who identified himself as an employee of the Central Intelligence Agency (CIA) called the University of Washington asking to inspect Senator Jackson's archived documents housed there. He found a document labelled as classified and showed this to a librarian.[50] In February 2005, 22 years after Jackson's death, a five-person team including staff of the CIA, Department of Defense, the Department of Energy, and the Information

Security Oversight Office came to library to review all of Jackson's papers to remove anything still considered classified, or reclassified since then. The Department of Energy found nothing of concern, but the CIA blanked lines in about 20 papers and pulled 8 documents out of collection.[50][51][48][52][53] As of 2018, some files in the collection are available only to those regarded by the library as "serious researchers", who must first sign a release not to divulge some of the information contained in the files.[54][47]

University of Washington - Essay - Essay: A Legacy of Public Service (The Senator Henry M. Jackson Web Portal)

See [HE003J][GDrive]

Warren Magnuson and Henry Jackson began their careers in an era when the economies of the world were in deep depression. Both were of Scandinavian parentage, heirs of the progressive reformist tradition that has marked Washington State politics. That tradition embodied ingenuity and tenacity, openness to broad involvement in government (direct legislation, woman suffrage) to government intervention in economic and social development, and to a political system responsive to issues and personalities rather than to party. Both endorsed President Franklin Roosevelt's leadership in creating programs to relieve the effects of the Great Depression, and they were known as "New Deal Democrats" throughout their careers. Their tandem representation of Washington State is remarkable both for its length and for the breadth of their interests in Congress. What follows is a summary view of their activities during forty years of unparalleled change.

Jackson's Early Years

Henry Martin Jackson was born in 1912 of immigrant Norwegian parents, Peter and Marie Jackson. In Everett, his hometown teachers and friends remember him as a good student with early ambitions to become president or a U.S. senator. His father was a concrete mason, and in the constrained economy of the time, young "Scoop" (as his sister Gertrude nicknamed him) delivered newspapers to add to the family income. He briefly attended Stanford University, then worked his way through the University of Washington to a law degree.

While awaiting the results of his bar examination in 1935, Jackson served as a caseworker in a Snohomish County relief office. During his second year as a lawyer with a private firm in Everett, Jackson and his friends mounted an innovative door-to-door campaign that culminated in his election as Snohomish County prosecutor in 1938. His insistence on strict enforcement of gambling and liquor regulations secured his reputation for integrity and yielded yet another nickname, "Soda Pop," an allusion to his sparing use of alcohol.

In 1940, Jackson ran for the Second Congressional District seat vacated when Mon Wallgren sought election to the Senate. Campaigning as a supporter of New Deal programs and publicly owned utilities, Jackson defeated five other Democrats in the primary and his Republican opponent in November. Jackson's first committee assignments in the House conformed with his interests in fishing, small business, and flood control. He enlisted in the army in 1943, but was recalled to Congress after basic training, in 1944. Jackson joined a fact-finding mission which witnessed the horrors of Buchenwald a few days after its discovery by allied forces. Visiting Norway after its liberation, he observed the repatriation of Red Army soldiers captured by the Nazis. "I recall how reluctant most of those Russians were to go back to Russia," he later noted. "They knew they'd have even less freedom there." These firsthand encounters with totalitarian systems and the wartime occupation of his ancestral homeland were reference points for Jackson's view that government was responsible not only for the provision of social and economic justice but also for the adequate defense of its citizens. "The first priority is survival. I feel we can do both," he said.

Postwar Adjustments

The tensions and irritations that followed the death of FDR and the end of the war in 1945, including shortages of housing and consumer goods and inflation, were acute in Washington State. The population of the state grew by more than a million after 1935, and while the housing boom spurred the lumbering and construction industries, the major issue was jobs. Thousands of returning servicemen discharged from military service stayed in the state to take advantage of the GI Bill. Moreover, defense contractors laid off workers as they struggled to make the transition to peacetime pursuits.

Breaking ground in a bulldozer, Hanford, ca. 1960s

Senator Magnuson and Representative Jackson supported Truman administration efforts to redirect the economy. But voter discontent with the slow pace of reconversion extended into the 1946 elections. Jackson's personal popularity among the predominantly Scandinavian fishermen, loggers, and dairy farmers of his district enabled him to survive. He won reelection to his third term, the only Democrat elected from the Pacific Northwest. The election of a Republican Congress, however, reopened many questions about New Deal reforms and the extent of federal involvement in state and local affairs and in the regulation of private enterprise

Power to the West

One of the great disputes of twentieth-century U.S. history has been waged among public and private purveyors of electricity. In Washington State, the idea of building an irrigation and reclamation dam at Grand Coulee had been around since the turn of the century. Columbia Basin development advocates, such as Rufus Woods of Wenatchee and Albert Goss of the Washington Grange, joined forces with public power proponents, such as Sen. C. C. Dill and Homer Bone to boost the project at state and federal levels. FDR backed with action his own view that public power projects served to moderate the cost of electricity. His support for the Bonneville and Grand Coulee dams and his authorization of McNary and four dams on the lower Snake River in 1945 laid the foundation for a comprehensive hydroelectric, navigation, reclamation, and flood-control program in the Columbia Basin. But the Bonneville Power Administration (BPA) and the federal power concept were under attack in the Congress after 1947, and appropriations to complete Columbia Basin projects were withheld.

In the wake of the great Memorial Day flood of 1948 and the power shortages later that year, as well as his own reelection, President Truman revived proposals for a Columbia Valley Authority (CVA). Magnuson introduced the legislation in the Senate, and Jackson in the House, in 1949. Backed by agricultural, labor, and public power groups, they argued for the revenues and regional productivity benefits accruing from such a multipurpose system. "The Columbia Basin project is good for the nation as a whole," noted Magnuson, "the biggest bargain since Seward bought Alaska." But a system similar to that in the Tennessee Valley was not to be. Congress did approve the River and Harbor Flood Control Act of 1950. The act authorized projects in sections of the nation besides the Pacific Northwest and included plans for Chief Joseph, The Dalles, and John Day dams. Although the CVA idea faded, the role of the federal government in Washington State power and resource development remained central to the work of the Pacific Northwest congressional delegation in future years.

Science and the Federal Government

Besides continuation of such public projects as housing and flood control, Truman's postwar domestic agenda included unification of the armed forces through the Department of Defense, the formation of the Atomic Energy Commission, and promotion of research in each of those areas through the creation of the National Science Foundation.

After the first atomic bombs were dropped on Japan in 1945, Congress supported international cooperation for future development of atomic energy. The reactor at Hanford produced plutonium for Atomic Energy Commission uses, and Representative Jackson became interested in the military and peaceful applications of the atom, including its potential for generating electricity. He won appointment to the Joint Congressional Committee on Atomic Energy in 1948. After the USSR detonated its first atomic bomb in 1949 and prospects for international cooperation receded, Jackson advocated expansion of military research, including the hydrogen bomb program. "If strength is the road to peace, then let's not waste a minute getting strong," he reasoned. "If peace comes, we can dismantle our atomic warheads and use the same material to run machines, treat cancer, fertilize the soil and for dozens of other productive jobs."

Truman's proposal for a National Science Foundation (NSF) grew out of the federal research experience of the 1930s and wartime. It was a direct successor to the Office of Science Research and Development that FDR created in 1941 to coordinate and protect research with military applications. As a new member of the Commerce Committee, Senator Magnuson introduced legislation in 1945 for government-funded science research and education. Testimony from scientists during Commerce Committee hearings on this measure underscored his belief that sophisticated research and international cooperation in the emerging Cold War era would not be adequately advanced by isolated government laboratories and private industry. Arguments about the propriety of federal support of research, the administrative structure of the agency, patent rights, and the loyalty-security issue took years to resolve. After the National Science Foundation was established in 1950, NSF grants became the engine for a broad national program of basic research and for the training of succeeding generations of scientists.

Magnuson and Jackson supported President Truman's "Fair Deal" agenda in other areas as well. Congress enacted the Displaced Persons Act, which liberalized immigration, provided for low-income and rural housing and slum clearance, raised the minimum wage to 75 cents an hour, and increased Social Security benefits and extended coverage to ten million additional people. Magnuson and Jackson also endorsed Truman's foreign policy initiatives, including the Marshall Plan, the North Atlantic Treaty Organization (NATO) alliance, and U.S. involvement in the defense of South Korea.

The 1950s

Recriminations about the 1949 triumph of the communists in China, the stalemate on the Korean Peninsula, and the rearmament of the United States in response to the Cold War became key factors in the elections of 1952. The bipartisan consensus on foreign policy faltered amid charges that "communist subversives" and "twisted thinking New Dealers" undermined national security. The electorate chose Gen. Dwight D. Eisenhower to clean up "the mess in Washington" while in "the other Washington" Rep. Henry Jackson unseated Sen. Harry P. Cain. A former mayor of Tacoma and paratrooper during the Second World War, Cain charged that Jackson's record showed he was incapable of understanding the seriousness of the communist threat at home and abroad. Running on the slogan "Jackson will make a great U.S. senator," the Snohomish County Democrat relied on volunteers (Scoop's Troops) to pass out literature emphasizing his twelve-year record. Against Cain's charge that he was soft on communism for voting against a permanent House Un-American Activities Committee, Jackson posed his abilities as a lawyer that enabled him to fight communism without destroying individual liberties. **His role on the Joint Atomic Energy Committee and his proposal for an atomic plant at Hanford to power industrial development of the Tri-Cities area were important aspects of Jackson's campaign.** The general prosperity occasioned by consumer demand and expansion of defense appropriations to meet Cold War needs helped Jackson, and combined with his vigorous campaign on both sides of the Cascades, he won the Senate seat by a comfortable margin in a generally Republican year. President Eisenhower's victory resulted in slim GOP majorities in the Congress. The junior senator from Washington gained assignment to the Committee on Interior and Insular Affairs. His posting to the Committee on Government Operations and its Subcommittee on Permanent Investigations brought Jackson to national attention. Its chairman. Sen. Joseph McCarthy, had been making broad accusations since 1950 about government agencies harboring communists. He subjected alleged subversives to intense investigation but failed to substantiate his charges. Jackson opposed such unproductive investigations and joined his Democratic colleagues in protesting McCarthy's tactics. Public opinion turned against McCarthy after millions witnessed his televised attacks on the loyalty of army personnel, and in 1954, the Senate voted to censure him. The attitudes that sustained anticommunist crusaders like McCarthy, however, became part of the fabric of U.S. politics. Meanwhile, Magnuson had become chairman of the Senate Committee on Interstate and Foreign Commerce after the Democrats regained control of the Senate in 1955. He also chaired the Independent Offices Subcommittee on Appropriations that reviewed the activities of such agencies as the Federal Communications Commission, Federal Power Commission, Interstate Commerce Commission (ICC), and the Veterans Administration. Magnuson's positions gave him great influence in matters important to Washington State development, from fishing and merchant marine affairs to ports, aviation, and inland waterways. He steered shipping and shipbuilding for Pacific military projects to Puget Sound. When Washington cattlemen were threatened with increased freight rates, he intervened with the ICC. When the Highway Act of 1956 authorized a vast system of interstate highways, Magnuson made sure that Washington State's ferry system was included.

Holding a long petition, Washington, D.C., ca. 1950s

Magnuson and Jackson worked to diversify the state's economic base during the Eisenhower years, when the administration sought to limit federal spending through its partnership programs with private industry and local governments. Their actions included obtaining appropriations to continue federal hydroelectric and reclamation projects authorized in previous years. They helped build cooperative relationships among private and public agencies that produced dryland port and irrigation districts. They used their influence in Congress to produce more-available bank loans, price supports, and import/export legislation responsive to the fishermen, orchardists, cattlemen, wheat ranchers, and lumbermen of Washington. Both senators responded to the economic development needs of Alaska because of its importance to the Washington State economy. They supported the initiatives of territorial representatives in

building the Alaskan infrastructure of utilities, schools, and housing. As chairman of the Interior Subcommittee, responsible for territorial affairs, Jackson introduced statehood legislation for both Alaska and Hawaii in 1955. During the next four years, he worked to overcome bipartisan objections based on defense and racial issues. Southern congressmen feared that admission of Alaska would lead to admission of Hawaii, another racially diverse state, upsetting the civil rights balance in the Senate. Both states were admitted to the union in 1959. In the shift to Democratic control of the Senate in 1955, Jackson gained reassignment to the Joint Committee on Atomic Energy and moved to the Armed Services Committee. He became known for his advocacy of bipartisan foreign policy, speaking and writing often on defense and NATO affairs. Jackson supported the continued presence of U.S. troops in Europe. Moreover, he endorsed Eisenhower's strategy of deterrence, in part, through air power, and backed Adm. Hyman Rickover in development of atomic submarines. In the mid-1950s, Jackson worked to accelerate the U.S. intercontinental ballistic missile (ICBM) program. Soviet "firsts" in the space race, beginning with Sputnik in 1957, seemed to bear out his warnings that the U.S. missile program was lagging. Congress moved to close the technological and scientific "gaps" by creating NASA and by enacting the National Defense Education Act in 1958, making money available for improvements in science, mathematics, and foreign language programs. Similarly, at Atlantic Assembly meetings, Jackson advocated scholarship programs for exceptional students from NATO nations to foster scientific and technical education and the study of Asian and African languages.

The post-Sputnik years convinced Jackson of the need for more effective U.S. leadership in world affairs. In 1959, when he became chairman of the Government Operations National Policy Machinery Subcommittee, he and his staff studied the policy-making areas of the executive branch as they related to national security. Besides producing reports on the National Security Council, the State Department, and the Atlantic Alliance, the committee's studies helped shape Jackson's views on arms control, defense, and foreign policy.

The 1960s

Senator Jackson's growing reputation led to his emergence in 1960 as a contender for the vice presidency. Candidate John F. Kennedy, however, chose Senate Majority Leader Lyndon B. Johnson, who, he believed, improved Democratic chances in the South in his close race with Richard M. Nixon. Jackson was named chairman of the Democratic National Committee. The election of Kennedy, the first president to have come of age during the New Deal, seemed to signal a new era of reform.

From their positions on Senate committees, the Magnuson-Jackson team advanced the interests of Washington State during the Kennedy and Johnson administrations. **When Bangor, on the Kitsap Peninsula, was chosen as the base for Polaris submarines, Magnuson's legislation for assistance to communities impacted by federal employees helped build schools and housing.** As the children of the baby boom moved from elementary school to secondary school to higher education ages, the senators supported initiatives for federal assistance.

The senators also encouraged expanded Western power generation and interregional cooperation. As a member of the Interior Committee, Jackson worked with the Washington Public Power Supply System (WPPSS), the BPA, and administration officials to conclude the Columbia Storage Power Exchange agreement with Canada in 1963. The treaty ensured firm power capacities of downstream U.S. dams and allowed the sale of power throughout the Pacific Northwest and California through the west coast interties authorized by Congress in 1964. FDR's vision of slack-water navigation from Astoria to Clarkston became a reality as appropriations for the Lower Snake dams to complete that "new Northwest Passage" speeded up during the 1960s. Magnuson and Jackson also backed such projects as the giant third powerhouse at Grand Coulee that expanded the capacity of existing dams.

But concern about the ecological and fiscal costs of hydroelectric projects mounted. To meet the long-term power demands of the West, Senator Jackson's proposal for a dual-purpose reactor at Hanford was approved by President Kennedy. WPPSS became the managing partner with the Atomic Energy Commission to add the steam plant, and by 1966 the new production reactor began contributing to the Northwest power pool. Although the project was plagued with difficulties after 1971, Jackson spoke with pride of the effort: "There we literally did beat swords into plowshares and provided jobs."

Pushing a news car out of the mud, Mt. Rainier, 1963

The industrial and agricultural development of eastern Washington through dams and reclamation also provided residents and tourists with recreational facilities. Travel and tourism became a major industry, and Magnuson and Jackson endorsed state promotional programs from Westport to Walla Walla. When the citizens of Seattle hosted a world's fair in 1962, Magnuson obtained a $10 million subsidy to boost the Century 21 Exposition. The Pacific Science Center, centerpiece for the fair's "Man in Space" theme, showed off both the latest NASA triumph and the Washington aerospace industry. Magnuson also backed the 1974 world's fair in Spokane that promoted his perennial interests in Pacific Rim trade and environmental protection.

Within the month after the world's fair closed in October 1962, however. Senator Magnuson almost lost his bid for a fourth Senate term. His opponent was a neophyte politician, a thirty-two-year-old minister from Snohomish County whose youth and vigor inspired an enthusiastic corps of volunteers. Richard G. Christensen used television extensively, and advertisements showed him speaking to an empty rocking chair to depict both Magnuson's age and his refusal to debate. Magnuson embodied the old-style, cigar-smoking, pork-barrel political insider rather than a member of the New Frontier, and his bachelor life-style and reputation as a hard-drinking man seemed out of place to many voters. Beyond those factors, however, the election took place within days of the Cuban missile crisis and the threat of nuclear war played into the hands of the resurgent New Right, which decried Magnuson's liberal record. Eastern Washington voters supported Christensen, as did organizations that disapproved of Magnuson's work for such federal programs as Medicare. The senator's forty-eight-thousand-vote victory resulted from his traditional strength in urban western Washington, where labor, education, and maritime organizations heavily supported him.

Commerce Committee

The election of 1962 convinced Magnuson and his staff of a need to make changes to increase his effectiveness and visibility as chairman of the Senate Committee on Commerce. He added enterprising staff members to help him and other committee members identify and develop approaches to issues. Magnuson encouraged junior and minority party subcommittee members to develop workable bills and accommodated their concerns in final legislation as much as possible. "We seldom pass a bill in the Commerce Committee that isn't pretty well agreed upon," he noted. Although some senators objected that Magnuson's integrative approach "compromised" their legislation, most realized the value of the chairman's insistence on taking a unified committee to the Senate floor. His mastery of Senate rules and deference to the divergent views of his colleagues resulted in an unusually effective committee. During Magnuson's tenure - the longest continuous chairmanship in Senate history (1955-78) - more than two hundred measures he introduced became law. The Commerce Committee's work during this period resulted in such legislation as that creating the Corporation for Public Broadcasting, the Communications Satellite Corporation, Amtrak, Conrail, and the Department of Transportation.

Magnuson and his staff made consumer protection a central concern of the Commerce Committee. In 1966, he created and became chairman of a new Consumer Subcommittee. The Dark Side of the Marketplace, a book Magnuson wrote with Jean Carper in 1968, aimed to raise public awareness of the need for protection of the consumer's economic welfare, health, and safety. Such protection, he emphasized, also served the interests of responsible businessmen,

Among the many consumer measures passed as a result of subcommittee work were regulations on flammable fabrics for children's sleepwear, truth in packaging and labeling, generic drugs (to lower the cost of antibiotics), cigarette labeling and advertising, toy and auto safety, improved product warranties, packaging for poison prevention, and drinking water safety. He also helped create the Consumer Products Safety Commission (1972) and the Agency for Consumer Advocacy to represent citizens before federal agencies and courts.

Magnuson and his Commerce Committee staff also brought fresh approaches to his traditional interest in fisheries and maritime policy. The general course of his activities followed on the National Academy of Sciences oceanography report of 1959, which recommended an ambitious program of ocean exploration rivaling the federal effort in space science. Magnuson interested the maritime construction industry in his ideas and took testimony from marine and fisheries scientists scattered among federal agencies and universities. These efforts culminated in enactment of the Marine Resources and Engineering Development Act of 1966, which provided coordination of research, education, and planning for future oceanographic development. Magnuson also sought ecological safeguards through regulations on toxic substances and oil tanker construction and through prohibition of oil ports on Puget Sound. Long a proponent of measures to preserve and enhance North Pacific fisheries, he sponsored the bill that established the two-hundred-mile fishing jurisdiction in 1977.

Interior Committee

Concern about conservation of natural resources preoccupied reformers at regular intervals in U.S. history—from the establishment of the National Park Service in 1916 to the New Deal's extensive soil and water management programs. Wilderness preservation and conservation forces found support in the Kennedy-Johnson administrations for new programs to solve the nation's growing ecological problems. Finding a balance between environmental concern and economic development became a major task for the Senate Interior and Insular Affairs Committee. Jackson's tenure on this committee began in 1953. He served as its chairman from 1963 to 1980 and helped guide a wide range of environmental protection bills through Congress. The Wilderness Act of 1964 set up a system for designating wilderness areas on public lands. It was followed in 1965 by the creation of the Land and Water Conservation Fund to buy and develop land for preservation and recreation. Additions to the Olympic National Park, wildlife refuges, and public-access facilities in parks were provided by the fund. Jackson responded to the persistent efforts of such Washington advocates as the North Cascades Conservation Council to forge the compromise that established the North Cascades National Park in 1968. That same year, he sponsored, with congressional colleagues, the National Wild and Scenic Rivers Act and the National Trails Systems Act. A program that provided city youths with jobs in the nation's parks and forests resulted from the Youth Conservation Corps Act of 1970. This measure depended on the persistent legislative teamwork of Jackson and Washington Congressman Lloyd Meeds as well as on the appropriations strategy of Magnuson and Julia Butler Hansen.

The landmark National Environmental Policy Act of 1969 (NEPA), which also was a Jackson-created bill, established environmental protection as a priority. The act required all government agencies to consider the impact of proposed programs on the environment and to seek any needed protective alternatives. Legislation of such sweeping character as NEPA was not easily passed. Timber, ranching, and mining interests and agencies such as the Corps of Engineers and the Atomic Energy Commission argued that efficiency would be hampered by such close regulation.

The preoccupation of the Interior Committee with energy issues after the embargo imposed by the Organization of Petroleum Exporting Countries in 1973 was indicated by its title change to the Energy and Natural Resources Committee in 1977. Jackson's ability to achieve bipartisan consensus was demonstrated by the passage of the Surface Mining Control and Reclamation Act of 1977, after hearings and attempts that spanned the previous decade. His reputation as an arbiter, as well as his credibility as an advocate for Alaskan development, helped in the mediation of the land claims of Alaska natives (1971) and in passage of the Alaska National Interest Lands Conservation Act (1980).

Influential Advocates

Washington's senators were often called "the gold-dust twins" or the "senators from Boeing" because the legislation they initiated or supported often directed federal monies to Washington State. Their reputation for backing programs in the national interest, as well as their accumulated seniority, were factors in the deference accorded Magnuson's economic development programs and Jackson's programs for national defense. Both were consensus seekers known for their ability to build coalitions supportive of their bills.

During a tour of military installations, Korea, 1955

Both were active in Democratic party affairs and were friends and advisers to presidents. Magnuson played poker with FDR, whose affectionate use of the nickname "Maggie" was widely adopted by others. He went fishing with Harry Truman and swimming with John Kennedy. President Lyndon Johnson, who began his congressional career with Magnuson on the House Naval Affairs Committee in 1936, was best man when Magnuson married Jermaine Peralta in 1964. While both senators supported the domestic reforms of the 1960s, Kennedy and Johnson drew on Magnuson's unique position and reputation to pass civil rights legislation. Lunch-counter sit-ins and freedom riders in Southern states focused national attention on the drive to desegregate public facilities. As a result, the public accommodations section was introduced as a separate bill to ensure hearings in Magnuson's Commerce Committee rather than in the Judiciary Committee, known as "the civil rights graveyard." The strategy produced a public accommodations section that Congress adopted as part of the Civil Rights Act signed by President Johnson on July 2, 1964.

Jackson's advice on defense and foreign policy was sought by both Democratic and Republican administrations. While both senators were proponents of a bipartisan approach to global affairs, their contrasting views were illustrated by their positions on the Vietnam War and China. Magnuson endorsed a strong U.S. naval presence in the Pacific and such alliances as Southeast Asian Treaty Organization (SEATO) and Australia-New Zealand-United States alliance (ANZUS) to contain communism and maintain trade. After the Vietnam conflict escalated to involve more than half a million U.S. troops, and his old friend LBJ decided not to seek reelection in 1968, Magnuson joined those advocating a negotiated U.S. withdrawal.

Jackson initially stood by LBJ in his conduct of the war as a means to check the domination of Southeast Asia by the Chinese and Soviets. As a member of the Armed Services Committee, he endorsed the bombing of North Vietnamese military targets until the South Vietnamese could defend themselves. He believed in "going for the jugular," because the Korean experience had shown the American people would not support a protracted war. As the war dragged on, he advocated a mutual cease-fire and a negotiated settlement; in 1968, he privately advised the Johnson administration against sending more U.S. troops. Jackson continued this stance with President Nixon while supporting Nixon's effort to "Vietnamize" the war and withdraw U.S. ground troops. Jackson declined Nixon's invitation to serve either as secretary of defense or as secretary of state. In 1972, he lost the party's nomination for the presidency to Senator George McGovern, a leading opponent of the war.

Magnuson's experiences in China as a young man and in the Pacific theater during World War II helped him realize the implications of U.S. domestic policy in international affairs. In 1943, he sponsored legislation repealing the Chinese exclusion laws, which were used by the Japanese to illustrate U.S. prejudice

against its Asian ally. After the Chinese communists conquered the mainland in 1949, the United States recognized the nationalist government, which had retreated to Taiwan Magnuson, however, advocated nonstrategic trade and cultural relations with the mainland Chinese as early as 1956. His overture was politically unpopular, but he maintained his belief explaining, "We can't keep four hundred million people behind an economic bamboo curtain forever just because we don't like the policies of their government."

By 1969, the shifting alliances of the Cold War era and the geopolitical importance of China had convinced Jackson that closer U.S.-China ties were crucial to U.S. efforts to promote world stability. He agreed that the Chinese could help end the war in Southeast Asia and applauded President Nixon's visit to China in 1972. In July 1973, Magnuson led the first U.S. congressional delegation to the People's Republic of China in nearly twenty-five years. Jackson made four official trips to China between 1974 and 1983. Throughout the 1970s, Jackson led discussions regarding normalization of relations, and the two nations finally exchanged ambassadors during the Carter administration in 1979. Magnuson and Jackson were instrumental in arranging many business, educational, and community contacts between the Pacific Northwest and the People's Republic of China and became revered figures in China.

Arms Control and Human Rights

The ideological rivalry between the U.S. and the Soviet Union was complicated by nuclear weapons, and negotiations in search of a solution to the arms race became a fixture of foreign policy. In the aftermath of the Cuban missile crisis in 1962, President Kennedy and Premier Nikita Khrushchev resumed long-stalled discussions on nuclear testing and formally signed a treaty the following October. The treaty banned atmospheric, ocean, and space testing of nuclear weapons while permitting underground testing. In the course of debate on ratification, Senator Jackson led those who favored the treaty contingent on administration assurances that U.S. testing and monitoring capabilities would be maintained and improved. His floor speech endorsing the treaty helped ensure ratification of the Limited Nuclear Test Ban Treaty.

In 1969, the two nations again entered arms control negotiations. Phase one of the Strategic Arms Limitation Talks (SALT I) concluded in 1972 when President Nixon and Secretary Leonid Brezhnev signed a treaty limiting antiballistic missile (ABM) systems and a five-year interim agreement on the limitation of strategic offensive arms.

During the Senate ratification process, Jackson voted with the majority to ratify the ABM treaty. He supported the interim agreement, but only after the Senate had agreed to his amendment directing the president to achieve equality in levels of intercontinental forces in all future agreements.

As part of the relaxation of tensions, the two nations also began to normalize trade relations that had languished since 1951. Senator Jackson, a critic of the Soviet Union's violations of the human rights of its citizens, emerged as a leader of the opposition to the restoration of its most-favored nation status unless it met certain conditions. In 1972, Jackson introduced an amendment to the Trade Reform Act that denied most-forced nation status to countries that denied their citizens the right to emigrate freely. Jackson targeted the amendment in part at the "education tax" on Soviet citizens that was designed to stop the exodus of talented individuals. Jackson's linkage of human rights to a favored trade status touched off two years of debate that was complicated by Soviet encouragement of the attack on Israel by Egypt and Syria during Yom Kippur in 1973.

Jackson supported close ties with Israel after its formation as a separate state in 1948. Soviet intervention in the Middle East confirmed Jackson amendment supporters in their doubts about detente. Henry Kissinger, Nixon's secretary of state, argued against trying to influence Soviet internal affairs. A compromise was reached allowing the president to waive the requirements of the amendment when an individual nation moved substantially toward freer emigration. The Jackson-Vanik Amendment became law in 1974.

The Jackson amendment and the resulting debate about human rights, preferential trade, and the role of Congress in foreign policy were issues in the 1976 presidential campaigns. Jackson won the Massachusetts and New York primary elections but withdrew from campaigning after losing to Jimmy Carter in Pennsylvania. As president. Carter endorsed the concept of the Jackson-Vanik Amendment. Following Carter's negotiation with the Soviets of the SALT II agreement, Jackson again led the skeptics, criticizing the lack of reductions in ICBMs and the failure to respect the principle of equality of strategic forces. With the Soviet invasion of Afghanistan in 1979, Carter withdrew the SALT II treaty from Senate consideration.

Health Care

For Magnuson, the post- Vietnam era was a time to do rear-guard battle on the health-care front. Magnuson's first bill as a new representative from Washington State in 1937 was a cancer research bill cosponsored with his mentor. Senator Homer Bone. The National Cancer Institute established by passage of that legislation was an innovation. It embodied the idea that research into noninfectious disease was within the purview of the federal government and advanced the role of U.S. Public Health Service research by means of fellowships, private investigators, and medical schools. The wartime experience with battle casualties and draftees revealed the need for better national health care, and Congress passed the National Institutes of Health (NIH) bill introduced by Senators Magnuson and Lister Hill in 1948. Heart disease and mental illness were added to cancer as "dread diseases" to be conquered by the Public Health Service. In 1950, more institutes were added, and Magnuson's work for the National Science Foundation included a Medical Research Division to coordinate grant activities with the NIH.

During the next decade, Magnuson helped devise an effective network of activists and health professionals who countered opposition and exploited opportunities to further their cause. The Korean War validated Magnuson's advocacy for involvement of Veterans Administration hospitals in research and education. The development of a poliomyelitis vaccine by NIH researcher Jonas Salk proved the importance of biomedical research to millions of parents. The health-care lobby also helped pass the Medicare and Medicaid programs over the objections of those who feared "socialized medicine."

Magnuson's ability to influence health legislation increased when he became chairman of the Appropriations Subcommittee on Labor-Health, Education, and Welfare in 1969. In opposition to Nixon administration budget cutters, he sponsored and helped guide through Congress new programs for rural and children's health-care. In 1973, he stopped Nixon's campaign to close the nation's Public Health Service hospitals. During these years, Magnuson became known as the "most-vetoed senator."

Magnuson took his arguments for increased health-care appropriations to the public with the book How Much for Health?, co-authored with Elliot A. Segal in 1974. The book served as a summary of the current state of the nation's health-care system and as a guide for future action, including the need for better food safety, lead-based paint regulation, and fire prevention. Magnuson's efforts on behalf of national programs did not overlook Washington State. Besides keeping open the Public Health Service Hospital, he obtained matching funds for the Fred Hutchinson Cancer Research Center in Seattle and endorsed appropriations for clinics such as those on the Puyallup and Lummi Indian reservations. In 1978, the Board of Regents of the University of Washington named the Health Sciences Center in Magnuson's honor, an acknowledgement that his support for biomedical research and education was vital to its many programs in the Pacific Northwest and Alaska.

End of an Era

End of an Era

Senator Magnuson rose to his most powerful positions during his last three years in the Senate. In 1978, he became chairman of the Appropriations Committee while also serving on the Budget, Science, and Transportation committees. As the senior member of the majority party, he was third in line for the presidency in the otherwise largely ceremonial role of president pro tempore of the Senate in 1979-80. He continued to work on issues he considered to be in the long-term national interest: no-fault auto insurance, health-care insurance, and fisheries conservation.

But it was his position as appropriations chairman that claimed most of his time. President Carter's campaign pledge to balance the federal budget by 1980 received Magnuson's support. Magnuson expressed his determination to impose discipline on appropriations through increased oversight, confident that he and subcommittee heads could trim programs and critique spending requests. In response to queries about his new "frugal hand," Magnuson replied that he was a "closet conservative when federal spending is the issue." Budget cutting was popular in many states at the time. After Washington State voters limited revenue collections by passing an initiative in 1979, Magnuson introduced a bill tying federal spending to the gross national product. However, Magnuson was as generous as ever in assisting the Pacific Northwest in calamities of the moment. He engineered appropriations for new Hood Canal and West Seattle bridges (both accidentally destroyed in 1979), steered a $400 million contract to Todd Shipyards, and made $951 million available to assist government agencies coping with the effects of the 1980 eruption of Mount Saint Helens.

In response to criticism during the 1980 campaign that the Appropriations Committee had become the "Warren G. Magnuson Charitable Trust," Vice President Walter Mondale said: "Maggie assured me that he has decided to be scrupulously fair with federal appropriations. He has decided to divide them up 50-50-halffor Washington State and half for the rest of the country." Others noted that, "Grant is Magnuson's middle name." Such joking revealed the ambivalence some voters felt about Magnuson's ability to bring federal funds to bear on Washington problems. While Magnuson's reelection campaign was well financed by traditional groups in the labor, shipping, and fishing communities, actual voting support was diluted by the issues. Support of health professionals was divided; some physicians doubted that Magnuson's support for national health care plans was good for the nation. Regional economic problems associated with declining salmon runs and the shift of lumbering jobs to the South were heightened by the double-digit inflation, and they weakened Magnuson's traditional voting base. Some observers noted that a majority of voters were young or new to the state and thus immune to the tradition of voting for "Maggie." Those same voters, however, also had acquired the habit of voting for Magnuson's opponent, the state's highest elected Republican officeholder. Attorney General Slade Gorton.

Gorton rose to leadership of the moderate wing of the Republican Party during his ten years in the Washington State House of Representatives. Vigorous and articulate, Gorton's initiatives as attorney general included the establishment of an office of consumer protection, and earned him continuous reelection after 1969. In the 1980 race, Magnuson's age and declining health were factors in his defeat. The fifty-two-year-old Gorton jogged and cycled around the state, while Magnuson conducted a whistle-stop tour by rail. The seventy-five-year-old Magnuson rebutted observations on his age with the comment, "Age isn't a problem; it's a fact of life." Concerning the voters' mandate that ended his forty-four years in Congress, he concluded that is was “some sort of tidal wave. There is a time to come and a time to go.”

The 1980 election, with its shift to Ronald Reagan and the Republican Party, seemed to signal the end of the old New Deal reform coalition. An ironic consequence of the GOP tidal wave was that Henry Jackson became senior senator and leader of the Washington delegation to Congress for the first time-but lost his chairmanships.

As ranking Democrat on the Energy and Natural Resources, Armed Services, and Government Affairs committees, Jackson worked at issues ranging from the Columbia Gorge to Middle East tensions. He acted to block such Reagan administration proposals as the sale of the Bonneville Power Administration system to private interests and the leasing of wilderness areas for oil and gas exploration. As relations between the United States and the USSR deteriorated, Jackson joined with Senator John Warner to obtain the support of sixty- one cosigners to a resolution urging a renewal of arms-control negotiations. The bipartisan resolution advocated a long-term, mutual, and verifiable arms freeze at equal and sharply reduced levels. Also in response to national and local concern, he proposed the formation of a bipartisan commission on Central America to end the policy stalemate between Congress and the Reagan administration as well as to unify the nation. The final report of the bipartisan commission was dedicated to Jackson.

Senator Jackson died suddenly on September 1, 1983, during his forty-third year in Congress. He had just returned from China, and in his last press conference, that day, denounced the Soviet Union's action in destroying Korean Air Line's Flight 007 with its 269 passengers and crew. Congressional tributes to Jackson's memory included the naming of a Trident submarine, the federal office building in Seattle, and the Foundation for the Advancement of Military Medicine in his honor. Moreover, in 1986, Congress approved a $10 million grant to match private funds raised to support the Henry M. Jackson Foundation, which had been established in 1983 by his widow, Helen, and his friends and colleagues. The Jackson Foundation carries forward the senator's commitment to the advancement of education and scholarship in the fields of international affairs, environmental and resource policy, and other areas of interest to him. Jackson also had furthered programs of the University of Washington's School of Law and Graduate School of Public Affairs that promoted his interest in international education and training for foreign service. The University's School of International Studies was named for Jackson in recognition of his active support for its programs and its interdisciplinary approach to the study of world cultures.

On the occasion of what would have been Jackson's seventy-fifth birthday anniversary, May 31, 1987, former Senator Magnuson said, "I have lots of memories tonight. We were a team. It was rare that we voted opposite." Together, they recorded more than twenty thousand votes, and, in the matter of Washington State development, they seldom disagreed.

NOTE: This account of the careers of Senators Magnuson and Jackson was written by Jane Sanders in 1987 under the auspices of the University of Washington Libraries to accompany the exhibit based on the senators' papers administered by the libraries. Advisors for the exhibit and for the biographical essay were University of Washington faculty members Robert E. Burke, Department of History; Brewster Denny, Graduate School of Public Affairs; and Richard Ellings, Jackson School of International Studies; as well as Dorothy Fosdick of the Henry M. Jackson Foundation.

Wife - Helen Hardin Jackson

Source : HistoryLink : [HL005S][GDrive]

Helen Hardin Jackson grew up in New Mexico, received an excellent education, and after a brief first marriage, became a secretary to a senator in Washington, D.C. There, in 1961, she met and married Senator Henry M. "Scoop" Jackson (1912-1983), a Democrat from Everett. Helen became known as a hard-working wife, mother, and co-campaigner with her husband through his re-election campaigns and two unsuccessful presidential bids. After her husband's unexpected death in 1983, she established the Henry M. Jackson Foundation as a living memorial to him. The foundation assists public officials, diplomats, and journalists in addressing international problems and funds scholarships, visiting faculty, and other programs at the University of Washington's Jackson School of International Studies. Helen also took on a variety of leadership and philanthropic projects in and around Everett and during the 1980s and 1990s often hosted fundraisers in her home. The Helen H. Jackson Endowed Chair in Human Rights at the Jackson School of International Studies was created in 2008 to recognize her personal commitment to human rights. Helen Jackson was diagnosed with Alzheimer's disease in 2003, and health conditions prevented her from being as active and public in the community as she had previously been. Helen Jackson continued to reside in Everett, where she was widely admired for her graciousness, generosity, and leadership abilities, until her death in 2018.

Early Life and Education

Helen Eugenia Hardin was born in Clovis, New Mexico, on August 17, 1933, the only child of Marion Moody Hardin and Jeanne Hardin. She spent her early childhood in Hobbs, New Mexico. When she was 10 years old, Helen's family moved to Albuquerque, where her father served as president of the American Gypsum Company. Helen's maternal grandfather, Dr. Clyde Campbell, was a Methodist missionary who taught English and Bible studies at the University of Soochow in China from 1907 to 1911. Helen's mother was born in China, a place that has always held special interest for her. Helen credits her grandfather with instilling in her an early love of reading and literature.

Helen was a well-educated young woman. She attended the Hockaday School, a private college preparatory day and boarding school for girls in Dallas, Texas. She graduated from high school in Albuquerque, then studied for a year at Vassar College in Poughkeepsie, New York, before transferring to Scripps College in Claremont, California.

At Scripps she served as senior class president and graduated with a degree in English and philosophy in 1955. Helen returned to Scripps in 1976 to deliver a commencement address on "The Role of Women in Public Life." She earned a master's degree in English literature, specializing in Virginia Woolf, from Columbia University in 1958. While there, she studied under Mark Van Doren (1894-1972), a Pulitzer Prize-winning poet, writer, and critic, who had a profound influence on Helen's intellectual development. After graduating from Columbia, she worked as secretary to the editor of medical publications at Oxford University Press in New York.

First Marriage and Divorce

In April 1955, shortly before her college graduation, Helen became engaged to Dr. William Fuller from Albuquerque, who was a surgical resident at New York Hospital. The couple's five-year marriage ended in divorce, and Helen returned home to Albuquerque.

In 1960 she took a speedwriting course to improve her secretarial skills. Helen referred to this as a "ghastly part of my life" (*The Seattle Times*, March 8, 1972). She had an excellent education, but the sexism of the era limited her career opportunities to secretarial work. Helen's vocational training in Albuquerque nevertheless proved to be an important career move. She soon received an offer to work for Senator Clinton P. Anderson (1895-1975), a Democrat from New Mexico and a family friend. Helen relocated to Washington, D.C., in January 1961 to begin a new career in the nation's capital. The move was to have a profound effect on her life.

From Career Girl to Senator's Wife

Helen's first day on the job, January 4, 1961, was auspicious. Senator Anderson invited Helen to attend a swearing-in ceremony for new senators. In an elevator on the way to the ceremony she met Senator Henry M. "Scoop" Jackson, the Washington state Democratic senator, 21 years her senior.

Helen and Scoop made a striking first impression on one another. A few weeks later, he invited her to tea and then took her on several bicycling dates. The couple courted throughout the spring and summer of 1961. They rarely did anything extravagant "because Scoop was thrifty" (Kaufman, 128).

Single, successful, and 48 years old, Scoop was considered one of the capital's most eligible bachelors. That changed on November 27, 1961, when Scoop and Helen announced their engagement. They wed on December 16, 1961, in an intimate ceremony at the Central Methodist Church in Albuquerque. President Kennedy sent a telegram "extending heartiest congratulations to you and your bride on this happy day" (Kaufman, 128).

The newlyweds took a two-week honeymoon to Hawaii, where Helen found little respite from her husband's high-profile political life. Helen noted that "half the State of Washington appeared to be in Hawaii" (*Everett Daily Herald*, January 2, 1962). Senator Jackson talked to reporters and attended a briefing on antisubmarine warfare and the communist submarine threat in the Pacific. The newlyweds dined with several Washingtonians in Hawaii, including Commander and Mrs. John Riley of Everett and Commander Don McLain, aboard the U.S. naval destroyer escort USS *Whitehurst*. The lack of privacy or break from politics that the Jacksons experienced during their honeymoon became a recurring theme with which Helen graciously coped throughout their marriage.

The couple returned to Everett, Washington, Scoop's hometown, on January 2, 1962. This week-long visit was the first chance many Washingtonians had to meet the senator's new bride. Mr. and Mrs. Henry C. Gaul and Mr. and Mrs. Charles G. Westrom hosted a reception in the couple's honor on Sunday, January, 7, 1962, at the Gauls' picturesque Lake Stevens home. Guests traveled from as far away as California to attend the reception, eager to meet the young woman who took the bachelor senator off the market. The *Everett Herald* reported, "The lovely blonde who was just the right girl for Sen. Henry M. Jackson, won the hearts of many of his longtime, hometown friends Sunday afternoon" (*Everett Herald*, January 8, 1962).

Senator's Wife

The couple returned to Washington, D.C., on January 9, 1962, as Congress reconvened. The new Mrs. Jackson transformed the former bachelor pad at 2500 Q Street into a suitable family home. When Congress was not in session, the couple returned to Everett, where they lived with Scoop's beloved older sisters, Gertrude and Marie, at 3602 Oakes Avenue.

Being married to a hard-working senator was often challenging for Helen. She credited her year-long position in Senator Anderson's office with teaching her about political life and helping her learn cope with the challenges. She learned what a senator's life was like before she married one, and thus had a fairly easy time adjusting to her husband's long workdays and to managing the household alone.

As the wife of a prominent senator, Helen became a public figure in her own right. However, domestic life remained a top priority. She enjoyed decorating, entertaining, and even cleaning and ironing, but she was not particularly fond of cooking. After the birth of the couple's two children, Anna Marie (b. 1963) and Peter (b. 1966), childrearing and family became primary concerns. Helen believed strongly in being a good partner to her husband and a good mother to their children, as well as maintaining two households and managing the family's social relationships. She worked hard to strike a balance between the competing demands for her time, energy, and attention.

Charming, gracious, and publicly reserved, Helen played the part of a dutiful wife to an ambitious senator extremely well. She possessed a great deal of depth and intellect; however, the media often characterized her in simplistic and superficial terms. They focused on her svelte figure, attractive good looks, or decorating and fashion choices. Those close to Helen are quick to note her wry sense of humor, wit, and intellect, which the media often overlooked or rarely saw, especially in the early years of their marriage.

Setting Down Roots in Everett

In 1967 the couple purchased a large colonial revival house at 1703 Grand Avenue in Everett, where Helen Jackson continued to reside until her death in 2018. Scoop had strong Everett roots, and it was important to him to return to Everett as often as possible. The Jacksons split their time between Washington state and Washington, D.C.

Although not a Washington native, Helen quickly grew to love life in Everett. The small mill town offered a slower pace, the family had friends there, and the children had greater freedom than they did in Washington, D.C. The Jacksons' Everett neighbor, Jeanne Metzger, describes Helen as a very loyal member of the community. She has long been active and committed to her department of the Everett Woman's Book Club. The whole family enjoyed taking part in simple neighborhood activities, like caroling and trick-or-treating. Harry Metzger once noted that "Helen adopted his [Scoop's] sense of community. She was dedicated to staying here" (Kaufman, 187).

Candidate's Wife, Round One

When Senator Jackson officially announced his candidacy for the Democratic presidential nomination on November 19, 1971, Helen Jackson was thrust into the national limelight. She was enthusiastic about her husband's candidacy. "I think any woman would enjoy being First Lady," she told a reporter five months before the official announcement (*The Seattle Times*, June 27, 1971).

Senator Jackson had many assets that made him a suitable presidential candidate, not the least of which was his wife. Young, charming, energetic, and attractive, Helen campaigned actively with her husband as his "ever-cheerful sidekick" (*The Seattle Times*, March 8, 1972). Crisscrossing the country on Scoop's "campaign for common sense," Helen also managed to attend to her domestic responsibilities and their children.

Although many presidential hopefuls and their wives traveled and campaigned separately, for the 1972 election campaign, the Jacksons almost always campaigned together. Helen considered campaigning together good for the marriage because it united the couple in a common cause. Helen was adamant that she not make speeches for her husband. "You end up giving your husband's philosophy secondhand" (*The Seattle Times*, March 8, 1972). Helen cited day-care centers, the environment, and helping the elderly as her own top priorities if she were to become First Lady.

Candidate's Wife, Round Two

Senator Jackson won the Washington state caucuses in 1972, but lost in all other states. Undeterred, he remounted a stronger campaign in 1976. This time the Jacksons adopted a different campaign strategy, and the couple traveled and campaigned separately. As a result, Helen emerged as a more outspoken figure in the 1976 election than she had been four years earlier.

Because Helen was campaigning and speechmaking without her husband by her side, the public was able to gain greater access to her. They discovered a charismatic woman who expressed sincere professional and personal admiration for her husband, whom she called "Dear Heart" (*Seattle Post-Intelligencer*, May 8, 1975). She spoke more openly on a wide range of issues, from senior citizens to national defense. The public picture of Helen Jackson that emerged in the 1976 campaign contrasted dramatically with the "happy homemaker" persona of 1972 (*Everett Herald*, June 12, 1976). Some journalists covering the 1976 election described Helen's charisma and warmth as Scoop's secret weapon in the 1976 campaign (*Everett Herald*, April 2, 1976). She was able to charm and connect with audiences in a way her husband did not.

Helen believed it was her responsibility to inform the public on Scoop's views, whether or not she agreed with them. "Sometimes my opinions differ radically from Scoop's, but my job is to tell people what his opinions are. Otherwise when they get to the ballot box they will be confused. Did he say this? Or did she say this?" (*The Oregonian*, February 13, 1976). Abortion was one notable issue upon which Helen and Scoop disagreed. Scoop supported abortion only when the mother's life was at stake; Helen took a more pro-choice stance.

Jackson lost the 1976 Democratic presidential nomination to Jimmy Carter, and the couple was disappointed when Scoop was not selected as Carter's running mate at the 1976 Democratic convention. However, the family soon returned to its old routines, splitting time between Washington, D.C., and Everett. Helen remained an active force in Scoop's senatorial re-election efforts in Washington state.

Views on the Women's Movement

As the wife of a presidential hopeful during the 1970s, Helen was often asked to take a stance on the women's movement. Her responses suggest that Helen struggled internally to balance competing roles and priorities as a wife, mother, and public figure and to find a meaningful identity for herself within the burgeoning feminist movement.

She told one reporter, "At first it turned me off ... but they no longer consider housewives second-class citizens. I enjoy being a housewife, and I used to resent that" (*The Oregonian*, May 3, 1975). She reiterated her earlier aversion to the women's movement a few months later, stating, "At first it was such a shrill movement that it turned me off. Now that the emphasis seems to have settled on a woman doing what is right for her -- that she should have a say in what she'll do with her life, then I applaud it" (*Everett Herald*, September 2, 1975).

Helen appeared to embrace and accept the women's movement much more comfortably once she was able to find a place for her work in both the private and public spheres. Although not a feminist in the "bra burning" sense, Helen held strong convictions about equality of the sexes and had for many years (*Panorama*, June 5, 1976).

Congressional Wives for Soviet Jewry

Helen cited such relatively safe causes as the elderly and child care issues as her would-be platform as First Lady. After the 1976 election, she began to take on more controversial issues. In 1978 Helen co-founded a group called Congressional Wives for Soviet Jewry with Joanne Kemp (b. 1936), wife of Jack Kemp (1935-2009), a Republican congressman from New York.

The 45-member group lobbied for human rights in the Soviet Union. At a December 4, 1984, rally in Portland, Oregon, Helen stated:

> "The Soviet leaders are now systematically promoting anti-Semitism as state policy ... . They do so for their own reasons but perhaps because they think they can get away with it. They see little evidence that the world is paying attention" (*The Oregonian*, December 5, 1984).

The group's goal was to work with other political wives from around the world to lobby to ease restrictions on Soviet Jewish emigration. The group and cause, while very much Helen's own, was nevertheless well-aligned with Senator Jackson's staunch anti-Soviet and pro-Israel positions.

Henry M. Jackson Foundation

Helen Jackson was widowed unexpectedly at the age of 50, on September 1, 1983. She wasted no time in ensuring that her husband's long legacy of political activism would not be forgotten. On October 25, 1983, she announced the formation of the Jackson Foundation to assist public officials, diplomats, and journalists in addressing international problems, and to fund scholarships, visiting faculty, and other programs at the University of Washington's Jackson School of International Studies. The foundation was created with $600,000 left over from the senator's 1982 re-election campaign funds. Helen headed the foundation and devoted herself full-time to raising $10 million in private donations in its first two years.

For Helen, the foundation was a means of following through on her husband's unfinished agenda and cementing his legacy in state and national history. She shaped the foundation's mission to address concerns of interest to the late senator, such as foreign policy, national security, energy, and the environment. Helen called the foundation a "living memorial for Scoop" (*The Oregonian*, November 17, 1985). In creating the foundation and assuming responsibility for its major fundraising goals, Helen Jackson successfully stepped from the sidelines, where she had comfortably spent many years, and into the forefront of political action. The foundation -- and the commitment to keeping Scoop's memory alive -- gave her life a new direction and purpose.

Helen Jackson served as chairman of the board of governors for the foundation for more than a quarter century. Her children, Peter H. Jackson and Anna Marie Laurence, served with her on the board. In its first 28 years of operation, the foundation granted more than $22 million to nonprofit organizations and educational institutions in the United States and Russia. Grant-making and strategic initiatives fall in four program areas, all of which reflect the senator's interests: international affairs and education, environment and natural resource management, public service, and human rights. The foundation and its many successes would not have been possible without the dedication, resourcefulness, and fundraising talents of Helen Jackson.

A Chair in Her Honor

On March 18, 2008, the Henry M. Jackson Foundation announced that it would donate $1 million to the Henry M. Jackson School of International Studies at the University of Washington to endow the Helen H. Jackson Chair in Human Rights. The endowment provides funding for a full-time professor to teach on human rights issues.

The endowed chair was a fitting recognition of Helen's impressive leadership talents and also provided the necessary momentum to create a permanent home for the study of human rights at the University of Washington. The Center for Human Rights opened in 2009 within the Jackson School. It is a strong testament to Helen Jackson and her family's long commitment to human-rights advocacy.

At Home in Everett

Although she was neither born nor raised in Everett, Helen Jackson adopted it as her permanent hometown. When her children were young, she enjoyed setting down roots in Everett with her husband and becoming part of the community. Helen remained close with Henry Jackson's sisters, Gertrude and Marie, and later brought her grandmother to live in the family home on Oakes Avenue. She adopted Everett, and it in turn adopted her. She recalled, "I'll never forget the way the people of Everett rallied to my side when Scoop died" (*The Seattle Times*, May 27, 1987).

Helen's philanthropic work and community activism peaked in the 1980s. In addition to chairing the Henry M. Jackson Foundation, she became actively involved in a number of civic and charitable organizations, such as the Everett General Hospital (now Providence Hospital) and the United Way, as a board member, advocate, and fundraiser. She assumed a more active role in the Gertrude Jackson Memorial Fund after her husband passed away. Scoop established the fund in 1969 to honor his sister, who taught at Everett's Garfield Elementary School for over 40 years, by funding scholarships to deserving students in Everett. According to the Henry M. Jackson Foundation executive director Lara Iglitzin:

> "Helen in her own right has provided tremendous leadership, serving on hospital boards and playing a major role in many of the civic organizations in Snohomish County. She has always opened her home for fundraisers and was often asked to speak and provide leadership" (*The Seattle Times*, March 19, 2008).

Helen Jackson was diagnosed with Alzheimer's disease in 2003. Her declining health prevented her from remaining as active with the Henry M. Jackson Foundation and with the Everett community as she had been previously. Nevertheless, she remained an Everett icon, a beloved local woman almost always described as "gracious" by friends, colleagues, and casual acquaintances. Helen Hardin Jackson died on February 25, 2018, at the age of 84.

2013 (Jan 31) - In remembrance of Dr Kuan-Teh Jeang (by Srimathy Sriskantharajah)

Source : [HW002T][GDrive]

Dr Kuan-Teh Jeang, Editor-in-Chief of *Retrovirology*, passed away on 27th January. We understand that Teh was well known and well liked by his friends and colleagues, so we would like to invite you share your memories and add your messages of condolences to this post. Below is a message about Teh from Dr Gottesman of NIH.

Dear colleagues,

Some of you have now heard the tragic news about Kuan-Teh Jeang of NIAID, who died suddenly and unexpectedly late Sunday night, on January 27. The cause of his death has not been verified, and I do not have the full details to relay.

I am sure you share my sense of shock and grief. Teh was 54 years old, had a remarkably productive scientific career, and was broadly admired on the NIH campus and in the field of virology and, in particular, retroviruses. I still can't believe, more than a full day after his death, that I am sending this kind of message about him to the NIH staff.

In my introduction for Teh for the George Khoury Lecture that he delivered in October 2012, I described him as a dynamo. He was chief of the Molecular Virology Section in NIAID's Laboratory of Molecular Microbiology, where he was a major figure in the fields of HIV and HTLV-1. In his 27 years at the NIH, he co-authored more than 300 publications and edited six books. He was the editor-in-chief of the journal Retrovirology, editor at Cell & Bioscience, associate editor of Cancer Research, and on the editorial board of numerousother scientific journals, including the Journal of Virology. He also was the recent past-president of the Society of Chinese Bioscientists in America, where he was outspoken in his desire for increased representation in leadership positions for Asian American scientists.

Teh's recent awards include the International Retrovirology Association Dale McFarlin Award in 2011, Biomed Central's Open Access "Editor of the Year" in 2010, and several Gates Foundation grant awards.

Teh's lab studies host factors that influence the pathogenesis of human retroviruses HIV-1 and HTLV-I. Some of his group's notable recent findings include: new insights into RNA modification and RNA-binding factors that affect HIV-1 post-transcriptional gene expression; successful genome-wide characterization of 252 human host cell factors in Jurkat T cells that are contributory to HIV-1 replication; and characterization of several oncogenic microRNAs and their contributions to HTLV-1 oncogenesis.

Teh had a colorful childhood. He was born in Taiwan, spent his childhood in Libya, came to the United States at age 12, and was accepted to the Massachusetts Institute of Technology at age 16. He arrived at the NIH in 1985 upon earning MD and PhD degrees from Johns Hopkins University. He was a postdoc in the lab of George Khoury, another great NIHer who tragically died young, for whom an NIH Wednesday Afternoon Lecture is named.

Teh's death is a blow to the NIH and the retrovirus research community; and our thoughts and condolences are with Teh's family: his wife Diane, a veterinarian with the FDA's Office of Regulatory Affairs, and his children David, John and Diana. We will keep you informed about any planned funeral or memorial arrangements.

Michael Gottesman, M.D.

Deputy Director for Intramural Research, NIH

Authors - Ben Berkhout, Monsef Benkirane, Andrew Lever, Mark Wainberg, Ariberto Fassati, Persephone Borrow, Masahiro Fujii, Srimathy Sriskantharajah & Matthew Cockerill

Dear colleagues

Our loyal friend Kuan-Teh Jeang, "Teh" to friends and colleagues, passed away unexpectedly at the age of 54 on the evening of January 27, 2013. Great shock and sorrow was apparent in the avalanche of email messages by the very many international colleagues with whom Teh interacted over the years. Many of us came to know Teh as an energetic and gifted scientist for whom we had much respect and affection.

Teh was born in 1958 in Taichung, Taiwan and was the youngest to his two older brothers. Teh spent his childhood in Libya and came to the US in 1970. At age 16, he began college at the Massachusetts Institute of Technology, and after two years, started medical school at Johns Hopkins University, receiving both his M.D. and Ph.D. degrees by age 25. His Ph.D. thesis was on the regulation of gene expression in cytomegalovirus with Dr. Gary S. Hayward as advisor. During his time at Hopkins, Teh met his wife, Diane, a graduate student in the same laboratory. They married in 1984 in Iowa, where Teh completed his medical internship. The next year, Teh started his post-doctoral work at the National Institutes of Health (NIH) in the laboratory of Dr. George Khoury at the National Cancer Institute. Dr. Khoury died much too early at the age of 43 in 1987, but he was Teh's role model and influenced him greatly in his professional life. As a recognition of his scientific achievements, Teh was recently selected to deliver the 2012 George Khoury Lecture at NIH on cellular transformation by the human T cell leukemia virus (HTLV-I).

Teh had been working at the NIH in Bethesda for 27 years, exactly half of his life, and was chief of the Molecular Virology Section in the Laboratory of Molecular Microbiology. His major research interest was around the human immunodeficiency virus (HIV-1) and HTLV-I, with an abundant production of more than 300 scientific publications on the molecular details of virus replication and relevant disease-causing mechanisms of viral pathogenesis. Teh was a true experimentalist with an interest in the implementation of new technologies to get to the next level of understanding of the biology of human pathogenic viruses. He only stopped bench work in 2004 when he became editor-in-chief of *Retrovirology*.

HTLV-1 is linked to the development of adult T-cell leukemia and a variety of inflammatory manifestations including HTLV-1 associated myelopathy. Teh was

the first to show that HTLV-1 transcription is regulated through the cAMP signaling pathway implicating roles for CREB and CBP before these proteins were clearly identified and cloned. His research team also contributed to our understanding of how the viral Tax oncoprotein activates the pro-inflammatory factor NF-kB. More recently, he proposed a role for deubiquitinases in the regulation of TRAF6–mediated NF-kB signaling. Teh's work has also advanced our understanding of genetic damage in virus-cellular transformation. In 1990, he first reported that the HTLV-1 Tax oncoprotein repressed DNA-repair. Thereafter, he characterized the important roles of dysregulated mitotic checkpoint and AKT activation in cellular transformation. His work has contributed to the elucidation of the role played by the spindle assembly checkpoint in oncogenesis, helping to explain how the loss of multiple checkpoints alters cancer tropism in vivo.

Teh had a long standing interest in understanding the viral and cellular factors that govern HIV-1 gene expression in infected human cells. In the late 1980s, Teh's lab showed that HIV-1 uses an unprecedented mechanism of transcription that is dictated by an RNA-binding protein, Tat, which binds a nascent viral RNA target (TAR), the first RNA enhancer element ever described. Subsequently, Teh's group characterized cellular RNA-binding proteins that regulate HIV-1 replication, including the TAR RNA binding protein (TRBP) that later became known as an important factor of the cellular RNA interference machinery. In recent work, his lab completed a genome-wide screening for human cell factors that are needed for HIV-1 replication. Using novel technology, Teh extended his interests in RNA-biology through the identification of small RNAs (i.e. siRNAs and miRNAs) that have biologically important roles in viral infection, cellular metabolism and virus-induced pathogenesis.

In addition to all these accomplishments, one of Teh's greatest contributions to science probably lies in his role as mentor for young scientists. Teh trained 37 international postdoctoral fellows and 7 more are currently working in his group at the NIH. He has been a fantastic mentor of young scientists who have since spread across the globe, from Taiwan to China, from France to the Netherlands, from Canada to many places in the United States. Many flew into Washington DC to attend the funeral ceremony on February 9th. Teh was attentive, supportive and kind, but at the same time, demanding to his postdocs. Importantly, he set himself as an unselfish role model for them, working essentially 7 days per week and regular working days ran from 7 am to 7 pm. But, also during the evening and at night, one never had to wait long for reply emails. He was truly interested and at many times influenced the future careers of those who were lucky enough to have spent some time in his laboratory. In fact, his words of advice reached many more individuals with whom he came across in his professional and private life. His mentoring commitment is also reflected in his service to many professional societies. For instance, Teh was a standing member of the AIDS Molecular and Cellular Biology (AMCB) Study Section, where he had a reputation for being strongly supportive of new investigators.

Teh always had a special interest in the area of scientific publication. For instance, in 1994 he joined the editorial board of the *Journal of Biomedical Science* (JBS) of the National Science Council of Taiwan, the country in which he was born. He was an avid advocate for ways to improve the journal's Impact Factor. He left this journal in 2004 to free himself for an important new activity: the launch of the journal *Retrovirology*, where he served as Editor-in-Chief since the journal's inception. From the earliest years, Teh was an advocate of the Open Access publishing format. In particular, at the helm of *Retrovirology*, Teh witnessed much skepticism in regard to Open Access publishing during the early years and indomitably championed the new publishing format while overcoming initial prejudice. Teh often referred to himself and his Editorial Board members as the 'Young Turks' of virology, pioneering a new and exciting publishing format. Unsurprisingly, his talent for kicking off new initiatives paid off and *Retrovirology* is currently among the highest cited journals in the field of virology, and all of this was achieved in less than 10 years. In addition, he served on the editorial board of numerous journals, including the *Journal of Virology* and the *Journal of Biological Chemistry*.

Teh – as all who knew him will attest – would never rest on his laurels and although *Retrovirology* had become a leader in its field, he pushed for more journal involvement with the retroviral community .... and Frontiers in Retrovirology was born in 2009. It was the first conference organized by a BioMed Central journal – another example of Teh taking the lead – and proved to be such a universal success that the 3rd conference in the series will take place in September 2013 in the UK in Cambridge.

Teh was a scientist with a vision and a broad interest in all aspects of scientific endeavor. He also was a true scientific leader, initiating scientific debate, writing editorials, sitting on many committees, orchestrating new book volumes and organizing international meetings on diverse topics. For instance, he was president of the Society of Chinese Bioscientists in America (SCBA) in 2010 and voiced the strong opinion that the representation of Asian-American scientists in leadership positions should be increased. He was instrumental in the decision to take the 2011 SCBA conference to China.

He was the recipient of an extraordinary number of awards, most recently the International Retrovirology Association's Dale McFarlin Award in 2011, BioMed Central's Open Access "Editor of the Year" in 2010 and the John's Hopkins University Woodrow Wilson Award in 2009. Teh was also elected to membership of prestigious societies such as the Academia Sinica in Taiwan, Fellowship in the American Academy of Microbiology, and Fellowship in the American Association for the Advancement of Science.

Teh had an infectious enthusiasm and winner's mentality both at work and play. He was a skilled tennis and chess player, a gifted writer, and a great debater with strong opinions on virtually all subjects of science and life in general. Additionally, he had a passion for current events and a love of travel, movies, food and music.

Teh's death is a blow to the retrovirus research community and we will sorely miss his scientific leadership. He has been central to so much of what we have accomplished together as well as being a supportive and generous friend to many of us individually. Teh's life was much too short, but his legacy and our memories of him will last forever. Our hearts and condolences are with his wife Diane and his three children David (23), Diana (20), and John (15).

A note from the Publisher

- Kuan-Teh Jeang was one of BioMed Central's first academic Editors-in-Chief, launching *Retrovirology* on our platform in 2004. From the very beginning, his level of enthusiasm and energy was extraordinary, and the results he achieved in developing *Retrovirology*showed he was just as much of a dynamo as an Editor as he was in the laboratory.
- Teh was a friend and close colleague to many at BioMed Central, past and present. His passing at such a young age caused shock and great sadness. He was simultaneously one of our most solid friends and supporters, while also being a tireless force driving change and improvement, reminding us not to sit on our laurels, and always ready with forthright but constructive criticism when he thought we needed to do better.
- Teh took a "24x7" approach, and he encouraged those he worked with at BioMed Central to do the same. In return, he was generous with praise and each Christmas he would recognize the BioMed Central team which supported *Retrovirology* with thanks and gifts. Teh's determination to make *Retrovirology* the leading journal in its field was striking, and his journal's continuing progress up the impact factor rankings gave him huge satisfaction and pride, culminating in June 2012 when *Retrovirology* overtook *Journal of Virology*.
- Teh recognized that, for open access to the results of scientific research to become a reality, a viable business model was crucial, and so he was always

supportive of BioMed Central's growth as a publisher. Introductions made by Teh helped BioMed Central to build its journal portfolio, especially in Asia, with *Journal of Biomedical Science* and *Cell and Bioscience*.

- The success of *Retrovirology* demonstrated that a strong Editor-in-Chief could build a scientific community around an open access journal. Teh encouraged BioMed Central to take this community-building into the physical realm by arranging a scientific conference in association with the journal. The 3rd *Frontiers of Retrovirology* conference will be held this year, and the event has provided a template for BioMed Central's growing number of successful journal-associated conferences.
- Teh was a deserved winner of our 2010 Editor of the Year award, which he celebrated in London at BioMed Central's 10th anniversary party (Figure 2). He will be sadly missed by all of us.

A Community Mourn The Death Of Dr. Kuan-Teh Jean

Dear colleagues,

Our loyal friend Dr. Kuan-Teh Jeang passed away unexpectedly on the evening of January 27, 2013. The following night and day an avalanche of emails went across the Retrovirus research community, starting in Australia, then Asia, Europe and America. Great shock and sorrow was apparent in the messages by the very many colleagues with whom Teh interacted over the years. Many of us came to know Teh (Additional file 1) as an energetic and gifted scientist for whom we had much respect and affection.

Teh was chief of the Molecular Virology Section in the Laboratory of Molecular Microbiology at the National Institutes of Health in Bethesda, USA. His major research interest was around the human immunodeficiency virus (HIV-1) and human T-cell leukemia virus (HTLV-I), with an abundant production of more than 300 scientific publications on the molecular details of virus replication and the disease-causing mechanisms. He trained over 30 postdoctoral fellows and had been a fantastic mentor of young scientists who have since spread across the globe, from Taipei to Hong Kong, from Montpellier to Amsterdam and from Montreal to Los Angeles.

Teh was a very dynamic and internationally oriented scientist and he always felt a special bond with the scientific community in Taiwan. He was born and spent his early childhood in Taiwan, and later learned to speak Mandarin fluently. He actively participated in the scientific review processes in the National Science Council and the National Health Research Institute and various universities, often travelling long distances to Taiwan to offer comments and suggestions on various aspects of science. He had deep affection towards his home land Taiwan and hence contacted the founding editor Prof. C.C. Chang and volunteered his service for the Journal of Biomedical Science (JBS) of the National Science Council of Taiwan, which was the only international journal sponsored by Taiwan government at that time. He joined the editorial board of JBS in 1994 and had been very influential since then. Teh was a stabilizing force during the formative years of JBS when the biomedical community in Taiwan was somewhat skeptical of an international journal with its Editorial Office based in Taiwan. After JBS was listed in the Journal citation Index in 1999, he was also an avid advocate for ways to improve its impact factor. It is largely due to his suggestions and sometimes unorthodox ideas that JBS jumped in the annual Impact Factor ranking. The creation of Vignettes, which was well-received by our readers, was one of those suggestions.

He left our board in 2004 to free himself for an important new activity: the launch of the Retrovirology journal, where he had been editor-in-chief since then. Again his talent to kick off new initiatives paid off and Retrovirology is currently among the highest cited journals in the field of virology, all achieved in less than 10 years. Since the early years, he had been an advocate of the Open Access publishing format. He was invited for the JBS editorial board meeting last September to present his current views on this topic and gave his most insightful suggestions. Teh always kept a special interest in Taiwan and its research activities, which led to several productive collaborations. He was also a champion for advocacy of the rights of Taiwanese scientists in international scientific organizations. He was elected as Academician of the Academia Sinica in 2008.

Teh was a scientist with a vision and a broad interest in all aspects of the scientific endeavors. He also was a true scientific leader, starting scientific debate, writing editorials, sitting on many committees, orchestrating new book volumes and organizing international meetings on diverse topics. For instance, he was president of the Society of Chinese Bioscientists in America (SCBA) in 2010 and voiced a strong opinion to increase the representation of Asian-American scientists in leadership positions.

Teh's death is a blow to the retrovirus research community and we will sorely miss his scientific leadership. He has been central to so much of what we have done together as well as being a supportive and generous friend to many of us individually. In his spirit, several initiatives have been proposed over the last couple of days by his students and colleagues to honor his legacy. Teh was only 54 years old and the loss is devastating for the Jeang family. Our thoughts and condolences are with his wife Diane and his children David, John and Diana.

Present and past members of the Editorial Board

Journal of Biomedical Science

2010 (June 30) - Chronic-Fatigue Link to Virus Disputed : Wall Street Journal - "One Research Group Finds Virus XMRV in the Blood of Syndrome Sufferers, One Does Not; Papers Held From Publication"

Source - [HN00SW][GDrive]

Two groups of researchers studying a potential link between chronic-fatigue syndrome and a virus called XMRV have reached contradictory conclusions, according to people familiar with the findings.

One group found a link, and the other didn't.

Their reports were held from publication after being accepted by two science journals—a rare move that has caused a stir among scientists in the field.

A paper published in October in the journal Science first identified XMRV in people with chronic-fatigue syndrome. Studies published later by other groups produced conflicting results on whether there was a link, leading to intense scientific debate over the Science report's meaning.

The Centers for Disease Control and Prevention estimates that between one million and four million people in the U.S. have chronic-fatigue syndrome, which is characterized by debilitating fatigue and chronic pain. Doctors tend to treat the symptoms, but there are no established, specific treatments.

Many patients, desperate for answers as to the cause of the condition, pinned a great deal of hope on the original findings.

Scientists at the Food and Drug Administration and the National Institutes of Health, including NIH infectious-disease specialist Harvey Alter, recently finished research that came to a conclusion similar to that of the Science paper—that XMRV, or xenotropic murine leukemia virus-related virus, is found in the blood of chronic-fatigue syndrome patients.

The paper was accepted for publication in the journal Proceedings of the National Academy of Sciences of the United States of America but is on hold, according to Ashley Truxon, media coordinator for the journal. She had no further comment.

Separately, scientists at the CDC, led by microbiologist William Switzer, concluded in a paper in another journal, Retrovirology, that they couldn't find XMRV in the blood of people with chronic-fatigue syndrome, according to people familiar with the situation.

Kuan-Teh Jeang, editor-in-chief of Retrovirology, said the Switzer paper went through peer review and was accepted for publication when he got a call from the authors earlier this month. They asked that the Retrovirology paper be held.

"My understanding was HHS [Department of Health and Human Services] wanted to get it straightened out. Both reports are from different branches of the government," Dr. Jeang said.

In an email between scientists familiar with the situation, viewed by the Wall Street Journal, a researcher said the two teams were asked to put their papers on hold because senior public-health officials wanted to see consensus—or at least an explanation of how and why the papers reached different conclusions, said the people familiar with the situation.

A spokesman for Department of Health and Human Services said the research was being reviewed. "All of these activities need to be completed in order to ensure HHS's commitment to the accuracy and relevancy of the scientific information it reports."

Dr. Switzer and representatives of the FDA, CDC and NIH said they couldn't comment until the papers were published. Dr. Alter couldn't be reached for comment.

Publication of results is considered a critical part of the scientific process, and researchers familiar with the situation said they were puzzled by the move. It is unusual for a paper to be held after it has already gone through the formal peer-review process and been accepted for publication, say scientists who publish frequently.

"It's fair to say it's not a usual kind of thing," said John M. Coffin, a special adviser to the National Cancer Institute and a professor at Tufts University in Boston who wrote an editorial alongside the Science report in October. Dr. Coffin said he couldn't comment specifically on the XMRV papers, but that scientists often come up with conflicting data, especially when a virus is new and not well understood as is the case of XMRV.

Fred Friedberg, who has chronic-fatigue syndrome and is president of the International Association for Chronic Fatigue Syndrome, said that because the science on XMRV and the illness wasn't yet clear, it is crucial that data on XMRV be published.

https://www.virology.ws/2010/06/30/publication-of-xmrv-papers-should-not-be-blocked/

Publication of XMRV papers should not be blocked

30 JUNE 2010

The findings by the NIH and FDA that XMRV is associated with chronic fatigue syndromehas been accepted for publication by the *Proceedings of the National Academy of Sciences* (*PNAS*). Release of the article has been blocked by *PNAS* due to work carried out by the US Centers for Disease Control and Prevention (CDC). That study, which was submitted to *Retrovirology*, failed to find a link between XMRV and CFS. Its publication has also been placed on hold. According to *ScienceInsider*:

The contradiction has caused "nervousness" both at *PNAS* and among senior officials within the Department of Health and Human Services, of which all three agencies are part, says one scientist with inside knowledge.

It is senseless to block publication because the two papers reach different conclusions. If both manuscripts were subjected to proper peer-review, and were deemed acceptable by the referees, then they should be published. The journal editorial offices must respect the opinions of the reviewers. By overriding their decisions, they have compromised the entire peer reviewer process.

Blocking publication also sends the wrong message to CFS patients, to the public, and scientists. Not only does this action raise suspicions about their motives – are they trying to publish only the result they believe is correct? – but it ignores the very important fact that science is self correcting. Scientists are humans, and they make mistakes. But eventually the right answer will come to the surface. And that is why *PNAS* and *Retrovirology* should respect peer review, publish the XMRV papers, and let science correct itself.

Xenotropic murine leukemia virus-related virus (XMRV) has been proposed to be associated with prostate cancer and chronic fatigue syndrome (CFS). This proposition has been controversial because many investigators have failed to replicate the reported associations. Here, we explore whether XMRV is an authentic human pathogen in the light of recent findings that indicate otherwise.

Main Text

Background

Xenotropic murine leukemia virus-related virus (XMRV) is a recently described gammaretrovirus that was originally detected in and molecularly cloned from a human prostate cancer (Urisman et al., 2006). A later paper reported that XMRV was present in the blood of 67% of patients with chronic fatigue syndrome (CFS) and in 4% of healthy controls (Lombardi et al., 2009). Since these publications, some investigators have detected XMRV in human prostate cancer samples while others have not (Silverman et al., 2010, Aloia et al., 2010). Aside from a single study that reported finding polytropic murine leukemia virus sequences (a virus related to but different from XMRV) in 87% of CFS samples (Lo et al., 2010), all other reports (at least seven) have failed to detect XMRV in CFS patients from Europe, China, and the U.S. (van der Kuyl et al., 2011).

The current state of XMRV as a human pathogen is controversial and remains confounding even to the most knowledgeable retrovirology aficionados. In this context, it is important to frame two separate issues for consideration. First, is XMRV a physiologically prevalent pathogen in humans? Second, based on where the virus has been detected in humans, is XMRV a passenger microbe or is it causal for prostate cancer and/or CFS?

XMRV Can Infect Human Cells

The receptor for XMRV is XPR1, a cell-surface protein ubiquitously expressed in many human and animal cells. Although XMRV was originally described as infecting human prostate stromal cells (Urisman et al., 2006), in vitro assays show that the virus can infect and replicate in various human, feral mouse, mink, monkey, and bovine cell lines (Stieler et al., 2010). A recent intravenous infection study of eight adult Indian rhesus macaques (five infected and three mock-infected controls) used immunohistochemical staining and in situ hybridization-based assays to show that the virus was widely disseminated in vivo. Infected tissues included lymphoid organs (CD4-positive cells) as well as the prostatic epithelium and reproductive tract (Onlamoon et al., 2011). These results show that XMRV has the capability to infect humans. Nevertheless, some of the controversy surrounding XMRV centers on the possibility that detection of this virus in human samples is due to contamination from mouse cells (Smith, 2010). A significant argument against this stance was the identification of 14 XMRV integrated proviral sequences in 9 human prostate cancers (Kim et al., 2008). However, a recent report showed that 2 of these 14 integrated proviral sequences were contaminants from an experimentally infected cell line that was propagated in the laboratory, raising the question of whether the other 12 reported XMRV prostate-cancer integration sequences may not also be erroneously tainted results (Garson et al., 2011).

Unlike other human pathogenic/oncogenic viruses such as human T cell leukemia virus (HTLV-1) or human papilloma virus (HPV) (Table 1), there is currently no conclusively reproducible epidemiological link for an XMRV-related human disease (prostate cancer or CFS) or a natural XMRV reservoir in humans, mice or other animals (Figure 1). In contrast to other "newly discovered" viral infections such as the severe acute respiratory syndrome (SARS) coronavirus or avian influenza virus, the infection source of XMRV for humans has remained elusive. Indeed, some investigators have argued that the high conservation of XMRV genome sequences reported from different geographic locales by multiple laboratories are inconsistent with significant infection or extensive replication of this virus in humans (Hué et al., 2010).

Equal versus equivalent access to the scientific literature

- Kuan-Teh Jeang

Retrovirology **volume 8**, Article number: 83 (2011) Cite this article

- **2384** Accesses

- Metrics details

The concepts of equal versus equivalent access to the scientific literature are discussed

In 1954, the United States Supreme Court in a landmark decision of *Brown vs. Board of Education of Topeka*, *Kansas* sharply repudiated the "separate but equal" principle of public education. The Court concluded that racially segregated education is "inherently unequal". In scientific publishing today, there exist two segregated means of knowledge dissemination --- the subscription journals and the Open Access (OA) journals. For those who can pay, there is immediate access to scientific papers published in both subscription and OA journals; those who cannot pay can access only OA journals. The status quo is thus an "inherently unequal" playing field between the "haves" and the "have nots".

How unequal is the current situation? In an August 1, 2011 posting on the *Nature News*website, Richard Van Noorden reported that "the proportion of research papers freely available is slowly and steadily creeping upwards... in 2009, it's above 28%. (Some of this literature is not immediately available at the time that it is published, because of journal policies that impose embargo periods on when material can become free)". The good news is that approximately 30% of published papers can be accessed freely. The bad news is that 70% of published, publicly funded research remains off-limits to those who cannot pay.

Can equal access be had by the "haves" and the "have nots"? To the extent that the subscription and OA tracks will likely co-exist, the foreseeable future is a "separate and unequal" reality. Without equal access, the next best goal is perhaps to achieve equivalent access.

What is equivalent access? Imagine two very similar papers reaching essentially the same conclusions; one is published in a subscription journal and the other published in an OA journal. The paying reader can read both papers; the non-paying person can read only the OA paper. This is "unequal" access. However, if the OA paper sufficiently conveys the same information as the subscription paper, then it is possible that "equivalent" knowledge is conveyed to both the can-pay and cannot-pay audiences.

The equivalent access concept works only if subscription and OA journals can attract and publish, in chronological proximity, similar articles of comparable quality and impact. Practically speaking, for this to occur, OA journals need to achieve quality metrics (e.g. Impact Factor numbers) that match their subscription counterparts. The *Retrovirology*experience suggests that such benchmark can be achieved (Figure 1).

Molecular Mechanisms Of Human Immunodeficiency Virus Trans-regulatory Proteins

Jeang, Kuan-Teh
National Institute of Allergy and Infectious Diseases

This project focuses on HIV-1 replication in cultured cells to develop understandings of viral pathogenesis and the cellular factors that influence viral gene expression. Examples of important scientific advances that we have achieved in the 2011 to 2012 period are outlined below. RNA helicases are ubiquitous in plants and animals and function in many cellular processes. Retroviruses, such as human immunodeficiency virus (HIV-1), encode no RNA helicases in their genomes and utilize host cellular RNA helicases at various stages of their life cycle. We have continued our study of RNA helicases in HIV-1 replication. We have identified several novel RNA helicases that activate HIV-1 post-transcriptional gene expression and an RNA helicase that represses HIV-1 replication through the interferon pathway. HIV-1 Tat protein recruits host cell factors including CDK9/cyclin T1 to HIV-1 TAR RNA and thereby induces HIV-1 transcription. An interaction with host Ser/Thr protein phosphatase-1 (PP1) is critical for this function of Tat. PP1 binds to a Tat sequence, Q(35)VCF(38), which resembles the PP1-binding """""""""RVxF""""""""" motif present on PP1-binding regulatory subunits. We have found that expression of PP1 binding peptide, a central domain of Nuclear Inhibitor of PP1, disrupted the interaction of HIV-1 Tat with PP1 and inhibited HIV-1 transcription and replication. We have identified small molecule compounds that target the """""""""RVxF""""""""-binding cavity of PP1 to disrupt the interaction of PP1 with Tat and inhibit HIV-1 replication. One of the compounds, 1H4, inhibited HIV-1 transcription and replication at non-cytotoxic concentrations. Our study shows that HIV-inhibition can be achieved through using small molecules to target a non-catalytic site of PP1. We have constructed several HIV-1 molecular clones, each containing a discrete cellular miRNA positioned in Nef. These retroviral genomes express the inserted miRNA and are generally replication competent in T-cells. The inserted intragenomic miRNA was observed to elicit two different consequences for HIV-1 replication. First, the expression of miRNAs with predicted target sequences in the HIV-1 genome was found to reduce viral replication. Second, in one case, where an inserted miRNA was unusually well-processed by Drosha, this processing event inhibited viral replication. Our work is the first study to examine in detail the replication competence of HIV-1 genomes that express cis-embedded miRNAs. The results indicate that a replication competent retroviral genome is not precluded from encoding and expressing a viral miRNA. In FY 2013, we published our findings that NEAT1 long noncoding RNA and paraspeckle bodies modulate HIV-1 posttranscriptional expression. Most of the human genome is transcribed into protein-noncoding RNAs (ncRNAs), including small ncRNAs and long ncRNAs (lncRNAs). Over the past decade, rapidly emerging evidence has increasingly supported the view that lncRNAs serve key regulatory and functional roles in mammal cells. HIV-1 replication relies on various cell functions. To date, while the involvement of host protein factors and microRNAs (miRNAs) in the HIV-1 life cycle has been extensively studied, the relationship between lncRNAs and HIV-1 remains uncharacterized. Here, we have profiled 83 disease-related lncRNAs in HIV-1-infected T cells. We found NEAT1 to be one of several lncRNAs whose expression is changed by HIV-1 infection, and we have characterized its role in HIV-1 replication. We reported that the knockdown of NEAT1 enhances virus production through increased nucleus-to-cytoplasm export of Rev-dependent instability element (INS)-containing HIV-1 mRNAs.

[HC004P][GDrive]

Rodney Joffe is the Chairman, Founder and Chief Technology Officer of **UltraDNS Corporation**. His operational responsibilities include defining and guiding the development of all technical initiatives within the company, as well as interaction with the standards bodies and working groups in the IETF, telecommunications, and network world.

Mr Joffe has been involved in the IT world since 1973 when he trained as a systems analyst and programmer in the Pensions Actuarial group of the Old Mutual Life Insurance Company in Cape Town, South Africa. **After co-founding Printronic Corporation of America (UK) Pty. LTD. in London, England, in 1977, he opened American Computer Group (ACG) - the first of his US based companies - in Los Angeles in 1983. He is still very involved in ACG as both the Chairman and acting CEO. ACG is one of the leading Data Processing Service Bureaus in the Direct Response advertising and marketing industry.**

In the early 1990's, following the NSF disgorgement of commercial Internet traffic from the NSFNet, he launched [Internet Media Network Incorporated] as the Internet division of ACG. In March of 1994, he established the first web-based online presence of a traditional mail-order company, Robert Redford's Sundance Catalog. In 1996 in partnership with Bechtel Enterprises, [Internet Media Network Incorporated] was renamed [Genuity Incorporated], which then went on to became one of the largest ISP Data Center Operators in the world. The company was driven by Hopscotch™, invented and patented by Mr Joffe, and the very first formal content distribution and load balancing technology. He remained as the Chief Technical Officer of Genuity until the end of 1997 when [Genuity Incorporated] was acquired by [GTE Corporation]. He was then appointed Vice-President, Strategic Technologies, and Chief Technology Officer of the Business Services division of GTE Internetworking.

Following his retirement from GTE Internetworking in 1999, he returned to Phoenix, Arizona, where he founded CenterGate Research Group, a technology think-tank that became the birthplace of UltraDNS, Catbird Networks, and a number of community focused services including GeekTools and the whois-servers.net project.

Mr. Joffe sits on the boards of a number of other technology companies, including Scientific Monitoring, an aerospace software company, and Plasmanet, one of the largest Internet database marketing networks.

In addition to his corporate activities, Mr. Joffe is a member of the Faculty Advisory Board of the USC Viterbi School of Engineering in Los Angeles, and the Advisory Board of the Postel Center at USC/ISI. He also serves on the ICANN SSAC (Security and Stability Advisory Committee) and is a member of the 2005 ICANN Nominating Committee.

Mr. Joffe is actively engaged in a number of Internet working groups and committees, including the IETF (Internet Engineering Task Force), OARC (Operations, Analysis, and Research Center), NANOG (North American Network Operators' Group), and ARIN (American Registry for Internet Numbers). He is involved in a number of initiatives to ensure the future of the Internet and is highly visible in the ongoing fight against spam, and similar attacks on Internet infrastructure and personal privacy. what is centergate ?

Source : [HC005N][GDrive]

CenterGate® Research is a group of entrepreneurial developers and engineers working on creating products and solutions designed to improve infrastructure performance for distributed computing.

CenterGate exists to improve the world of distributed computing.

The scope of CenterGate is as broad as the interests of its talented team. CenterGate funds and fosters the creative ideas of its founder, Rodney Joffe pairing his genius for technological innovation with the precise programming skills of some of the best minds in networking, systems engineering and software development.

CenterGate management pairs Rodney's strengths with the entrepreneurial vision and experience of angel investor Ron Lachman who brings his own zeal and enthusiasm to the business of marketing technology solutions. A developer himself, Ron mentors the CenterGate scientists in the product development process and oversees CenterGate business initiatives.

From enhancing fundamental Internet architecture services, such as the CenterGate UltraDNS system, to improving the desktop productivity of the individual user through the eFridge® online calendar, CenterGate is doing what others dream of, developing the solutions we all want and need.

Our latest adventure is Catbird Networks, a whole new breed of monitoring and measuring system for distributed computing.

2010 (July 14) - Application / Resume

NOTE - Rodney Joffe does not mention **Internet Media Network Incorporated** on his resume in 2010. Nor does he mention "American Computer Group".

Source - [HL005Z][GDrive]

NOTE - Most of this is repeated on the ICANN profile (as of 2020) for Rodney Joffe ; https://icannwiki.org/Rodney_Joffe

- Rodney Joffe is Senior Vice-President and Senior Technologist of Neustar, Inc (NYSE:NSR). He assumed this role after the acquisition in 2006 of UltraDNS Corporation, a directory services company he founded in 1999. His responsibilities include defining and guiding the technical direction of the company's Internet Infrastructure Services Group as well as heading the company's cybersecurity initiatives.
- Rodney is frequently called upon to assist Federal Authorities with regards to investigating and protecting against cyber-crime and cyber-terrorist activities where he is a recognized expert. He regularly briefs the White House and House/Senate groups on the subject, and has testified before congress as an expert. In addition to publishing a number of confidential papers in the field, he participated as a "Designated Trusted Agent" on the planning committee for the DHSs CyberStorm II International Cyber-Terrorism exercise in March 2008. He is participating in CyberStorm III as a lead on the core scenario design team.
- Besides these operational activities, Rodney is also active in Internet governance bodies, serving currently on the ICANN SSAC (Security and Stability Advisory Committee) and previously on both the ICANN RSTEP (Registry Services Technical Evaluation Panel) the ICANN NOMCOM (Nominating Committee) where he served three terms. He is a founding member of the Advisory Board of the Postel Center at USC/ISI, and is engaged in several Internet engineering organizations including OARC (Operations, Analysis, and Research Center), NANOG (North American Network Operators' Group), ARIN (American Registry for Internet Numbers), and the IETF (Internet Engineering Task Force). He holds a number of issued and pending patents in the network security field.

Employment

2006-Present: Neustar, Inc.
Sr. Vice President & Senior Technologist, and CTO, Internet Infrastructure Services Group

- Oversee all cyber security practices for the company
- Developer of Neustar technologies including UltraDNS Managed Services, DNS Shield, and the Cache Defender Cache Poisoning solution
- Responsible for design and architecture for DNS resolution
- Manage DDoS mitigation initiatives

1999-2006: UltraDNS
Founder, Chairman, and Chief Technology Officer

- Designed and developed the patented UltraDNS domain resolution system.
- Led development team from inception through sale of the company to Neustar in 2006.

1997- 1999: GTE Internetworking / [Genuity Incorporated]
Founder of [Genuity Incorporated], CTO of GTE Internetworking Business Services [a subsidiary of GTE Corporation]

- Founded one of the largest Internet Service and Hosting providers in the world
- Designed and developed the patented "Hopscotch" technology for DNS routing
- Served GTE Internetworking as CTO of GTE Internetworking Business Services when it acquired [**Genuity Incorporated**]

1984-current: Whitehat, Inc.
Founder and Chairman of Direct Marketing Service Bureau, (presently serve in an advisory capacity)

- Designed computer programs that migrated direct marketing database processes from main frame computers to desktop environments
- Invented the "add-a-name" file processing technology

Cybersecurity Expert:

- White House Advisor, CyberSecurity Issues: April 2010 – present
- DHS, FBI - March 2007 - ongoing advisory relationship
- Head of the Conficker Working Group - March 2009 – ongoing
- Congressional Testimony May 1, 2009 - House Committee on Communications, Technology, and the Internet on CyberSecurity issues
- Numerous Conferences and Symposia, Keynotes and technical presentations
- Cyberstorm III – Lead on the Core Scenario Design Team 2010
- Cyberstorm II - Planning and Exercise for DNS/Cybersecurity Scenario 2008

Internet Governance Service:

- 2004-Present - ICANN SSAC (Security and Stability Advisory Committee)
- 2006-2008 - ICANN RSTEP (Registry Services Technical Evaluation Panel)
- 2005, 2006, and 2009 - ICANN NOMCOM (Nominating Committee)
- 2004 –Present - OARC (Operations, Analysis and Research Center)
- 1993 – Present - NANOG (North American Network Operators' Group)
- 1997-Present - ARIN (American Registry for Internet Numbers)
- 1998 – Present - IETF (Internet Engineering Task Force)

Patents:

- Multi-tenant Unit - U.S. Pat. No. 6,144,638 issued November 7, 2000 [NOTE : This patent is shared with **Thomas Johannes Obenhuber (born 1955)** , and Obenhuber may have been the significant contributor]
- "Hopscotch" - U.S. Pat. No. 6,185,619 issued February 6, 2001
- Domain name resolution system and method - Pending - App No 20040039798
- Suspect Traffic Redirection - Pending - App No 20070097976

Presenter/Speaker:

- Keynote speeches at leading industry conferences – Cloud Connect 2010
- Presenter/Session leader for key Cybersecurity and DNS Conferences – RSA 2009
- Radio, Webinar expert interviews in the areas of Cybersecurity and DNS

NOTE : This story was only available because it was on the LATimes website - it is suspiciously absent from Newspapers.com

Iowa's attorney general said Friday that his office impounded about $800,000 from a Beverly Hills company selling overpriced grandfather clocks.

Atty. Gen. Tom Miller said more than 10,000 consumers sent checks and money orders to a Clinton, Iowa, address after receiving a post card saying they had won a "world-famous Bentley IX Grandfather clock." Consumers were asked to send $69.19 for shipping.

The clocks are worth far less than the shipping fee, Miller said, and it was just a scheme to sell the cheap clocks at an inflated price.

"We believe the card was deceptive because it created the impression that the consumer had won the grandfather clock," Miller said. "The card also seriously overstates the quality of the clock, which is battery powered, pressed wood and plastic."

Miller said his office filed suit and a consent judgment against Prize Redemption Warehouse of Beverly Hills and a related corporation set up in Iowa, Merchandisers Warehouse Inc., and that no consumer will lose any money.

Firm will refund $800,000 to Iowans

Attorney general sues to halt bogus grandfather clock offer

By Judy Daubenmier
Gazette Des Moines Bureau

DES MOINES — Iowa Attorney General Tom Miller's office has reached a settlement with a Beverly Hills company doing business in Iowa that will return approximately $800,000 to more than 10,000 consumers who believed they had won a grandfather clock.

Miller's spokesman, Bill Roach, said officials have impounded the mail ordering the clocks and it will be returned to consumers because the contest is believed to be a scheme to sell cheap clocks at an inflated price.

According to Miller's office, consumers all over the country were contacted with a postcard indicating they had won a Bentley Grandfather clock.

The postcard describes the clock as "the beautiful, five feet tall, world-famous Bentley IX Grandfather clock, complete with a fully encased pendulum, three weights and crafted in genuine old-world style wood grain finish."

> "We believe the card was deceptive because it created the impression that the consumer had won the grandfather clock."
>
> *Tom Miller, attorney general*

In order to receive the clock, the consumer was asked to pay $69.19 to cover shipping, handling and merchandising costs.

"We believe the card was deceptive because it created the impression that the consumer had won the grandfather clock," Miller said.

The attorney general said the consumers were merely buying a cheap, battery-powered, pressed wood and plastic clock at an inflated price.

The firm involved, Prize Redemption Warehouse of Beverly Hills, Calif., had set up an Iowa corporation, Merchandisers Warehouse Inc., of Clinton. Rodney Joffee was president of the Clinton firm and Linda Marilyn Carella was vice president.

MILLER CALLED the case unique because it involved a national scheme being operated from Iowa. Generally, he said, such schemes are set up outside the state and attempt to take advantage of Iowans.

After about a three-week investigation, the attorney general's office obtained a court order Jan. 22 impounding the mail as it was received.

A lawsuit and consent judgment filed Friday in Clinton County District Court ordered the return of the mail to consumers and enjoined the firm from continuing the scheme.

Iowa

Grandfather clocks sur(prize) winners

PROVIDENCE, R.I. (AP) — An Iowa-based mail-order company that sold grandfather clocks by claiming to give them away if the "winner" paid postage has been shut down, authorities said Tuesday.

The company, Merchandisers' Warehouse of Clinton, notified people by mail that they had won a grandfather clock and could claim their prizes by sending in $69.19 to cover postage and handling, Attorney General James E. O'Neil said.

The offer was deceptive because the value of the clocks was greatly exaggerated, O'Neil said in a news release.

"Postage and handling costs for these clocks would have been about $10 to $15, so customers were actually being asked to buy the clocks," he said. "Nobody was winning anything."

> *'You say grandfather clocks to people, they think of these big floor models. They thought they were getting a real deal.'*
>
> *— Tom Connell Rhode Island Attorney General's spokesman*

Tom Connell, a spokesman for O'Neil, said the clocks were "table-top things, worth about $50 to $60."

"You say grandfather clocks to people, they think of these big floor models," Connell said. "They thought they were getting a deal."

In a consent decree between the company and the U.S. Postal Service, the company agreed to stop the promotion and give consumers full refunds.

Connell said the company used mail drops in Smithfield; Fairfield, Conn.; Tucson, Ariz.; Albuquerque, N.M., and Memphis, Tenn.

About a dozen people from Rhode Island and six other states complained to O'Neil's office about the scam, citing the Smithfield mail drop, Connell said. He said he did not know how much business the company had done.

Merchandisers' Warehouse officials could not be located for comment. The owners, identified in court papers as Rodney Joffe of Beverly Hills, Calif., and Linda Carella of Los Angeles, do not have listed telephone numbers.

A recorded message at the company's Clinton, Iowa, office, began, "No doubt you are calling with a question or two about the grandfather clock you ordered."

"By now, you should have received a letter from the Iowa authorities, together with your order and check," the message said.

"When we originally offered you the grandfather clock, the government felt that our offer wasn't clear," the message said. "The letter you received from us gives you a second chance to order a grandfather clock, knowing all the facts."

The clocks are 5 feet tall and weight 27 pounds, the message said.

Answer to spam on Net developed by Phoenix firm

By Rebecca Rolwing
The Arizona Republic

Rik Pierce, 59, got an e-mail recently, titled "overdue bill."

Naturally, he opened the notice only to discover it was an advertisement for a pornographic web site.

He was the victim of spamming — unsolicited, unwanted junk e-mail sent in bulk to addresses around the world.

"This is something that's fundamentally wrong," said Rik's son, Tim, a systems administrator for a Web-based company. "It's annoying and destructive."

A Phoenix company, American Computer Group, on Monday introduced its solution to the problem at a direct marketing convention in San Francisco. It is creating a global list of people who are sick of unwanted ads. Advertisers can then match their target audience with names on the list to find out who doesn't want to receive the messages.

Entire domains also may sign up for the service, called SAFEeps, meaning that Internet service providers and businesses can block all junk e-mail from going to any of their addresses.

For a fee, direct marketing firms can send lists of e-mail addresses targeted for a mass mailing to ACG. The company will scour the list and delete the addresses of those who don't want the ads.

It costs firms $29.95 to check up to 300,000 addresses. Consumers can be added to the list free by contacting www.safeeps.com.

The service comes as the spamming industry is staring down the barrel of government-enforced regulation that could make all unsolicited e-mail ads returned to sender.

ACG's Rodney Joffe, who has worked in both the direct marketing business and the Internet industry, is optimistic the service will be a success even though there's no requirement for marketers to use it.

— *Please see* **SPAMMING,** *Page E10*

Spamming answer developed in Phoenix

— **SPAMMING,** *from Page E1*

"It's a compromise between the anti-spam groups of the world and the marketers of the world," Joffe said.

Hotmail Corp., a major Internet provider of e-mail services, has signed up for SAFEeps to keep its subscribers from getting the bulk e-mail.

People whose service provider has signed up for SAFEeps can ask to have their names taken off the list if they wish to receive the ads. Or they ask to get only unsolicited ads about a certain subject, like dogs or hunting.

Any changes to reduce spamming can't come soon enough for Pierce, senior systems administrator for RootsWeb Genealogical Data Cooperative. The company has 4,000 mailing lists that genealogists use to talk and swap information.

Spammers also use the lists. Last month, RootsWeb got slammed with 12,000 messages — that's about 40,000 pages of material.

"When we get one of these attacks, the machine goes crazy trying to process them all," Pierce said. As the computer struggles with the e-mail onslaught, it sometimes rejects messages by regular users.

Extractor Marketing, a Detroit company that sells spamming software, gives SAFEeps a partial endorsement.

"It's definitely a major step in the right direction," Extractor President Todd Farmer said. "But it's probably a little too strong if all the (Internet providers) in the world decide to enforce this system instead of allowing their users to make this choice."

SAFEeps allows direct marketers to weed out people who hate spam and wouldn't buy products presented to them through unsolicited ads, Farmer said.

The Coalition Against Unsolicited Commercial Email also gives the system a partial blessing.

"If an opt-out system can work, (SAFEeps) will very well work," said Ray Everett-Church, an attorney and a CAUCE co-founder.

Still, marketing companies are not required to use SAFEeps, meaning that people who don't want commercial e-mail will still get it, Everett-Church said. The coalition will continue to push for a national bill to bar spamming.

1998 (Dec 08) - NYTimes - "Marketers and Net Activists Reach Agreement on Spam"

By JERI CLAUSING , Source = [HN01GC][GDrive]

ASHINGTON -- Internet activists and direct marketers, who have been fighting for years over whether and how states and the federal government should regulate the growing use of unsolicited commercial e-mail, said on Monday that they had reached an agreement that they hope will produce consensus legislation and industry rules governing the contentious issue of Internet marketing.

The agreement was hailed as significant by all sides in the debate over unsolicited commercial e-mail, or spam. Those who participated in the meeting, which was held on Friday, included the head of the Direct Marketing Association (DMA), representatives of the Coalition Against Unsolicited Commercial Email (CAUCE) and an executive from Microsoft Corp.. They came away with a consensus that both "opt-in" and "opt-out" mechanisms, for accepting or declining to receive marketing messages, need to be put in place.

Anti-spammers have historically pushed for "opt-in" systems, where marketers can only send their pitches to people who have signed up to receive so-called junk e-mail. The Direct Marketing Association, on the other hand, has pushed for the "opt-out" alternative, which would only require marketers to honor the requests of Internet users who have specifically asked not to receive e-mail advertisements.

Both sides also pledged to support legislation which, at a minimum, would prohibits false identification of the sender of commercial e-mail messages.

And both sides have agreed to work toward creation of a nonprofit global "opt-out" list, supported by marketers and free to consumers, which would allow both business entities and individuals to perform a one-time global choice to reject receiving unsolicited commercial bulk e-mail. That system would allow entire domains to "opt out," meaning companies that own their own Internet addresses and e-mail systems could ask to keep their entire systems free of junk e-mail.

Rodney Jaffe, an Arizona businessman who organized the meeting between the president of the Direct Marketing Association and key anti-spam groups, called the agreement "significant."

"I think if you look at it from the 50,000-foot level, the most important thing is that it was the very first time that the people who are really involved in dealing with spam sat down with no preconceived notions, no rules," said Joffe, chairman of Phoenix-based American Computer Group, a service bureau for direct marketing companies.

Joffe said he was interested in helping the competing groups find common ground because he is involved with businesses on both sides of the issue.

"Hopefully, this will have turned out to have been the pivotal meeting that actually gets control of the spam problem."

Deirdre Mulligan, a lawyer for the Center for Democracy and Technology who at the request of the Federal Trade Commission led a yearlong working group that studied potential solutions to the spam debate, said she was heartened by the announcement.

"I think what this shows is that when there is a table created and people step back from the rhetoric, that there is a lot of agreement at least on how to start addressing the problem," Mulligan said. "A year ago CAUCE and DMA couldn't agree on anything."

Ray Everett-Church, a lobbyist for CAUCE, said "the starting point is that the DMA seems to have realized that 'opt-in' marketing methods are good marketing methods and are the kind of methods that increase consumer comfort levels for receiving marketing e-mail."

He said being able to convince the Direct Marketing Association to support a system that would allow entire domains to opt-out of marketing lists was also significant.

"We were able to show them that there are not only a lot of ISPs out there with their domains but even more businesses who own their own domains and all the equipment and e-mail addresses to which that mail might be sent," Everett-Church said.

The law would be the first in the United States setting out potential fines and prison terms for convicted spammers.

"So for instance, a large corporation might have an entire sales fleet with e-mail paging systems. If you can't opt out the whole domain, there is no way that a pager, for instance, could opt itself out. So you need to be able to do that at a domain level."

Robert Wientzen, president of the Direct Marketing Association, said a key point for his group was the "general agreement that this is not going to inhibit the growth of e-mail as a marketing tool. We believe there is a great future for e-mail marketing."

At the meeting, Everett-Church said, "We were able to show them that we're not wild-eyed crazy people but that we really are business people and we are concerned with the tactics but we are also in the business of making money and we understand what it takes to do that."

Everett-Church and Wientzen both said they hoped that through continued meetings the groups can reach consensus on legislation being prepared for Congress's return in January.

The groups were on opposite sides of the aisle during the 105th Congress, with CAUCE pushing for an outright ban on unsolicited commercial e-mail. The Direct Marketing Association backed alternative bills that would have required senders of bulk e-mail to label their messages as unsolicited commercial e-mail, and to contain accurate reply information to enable recipients to be removed from the mailing lists.

CAUCE had strongly opposed the Direct Marketing Association proposals, saying they would legitimize a practice that is costly not only to the Internet service providers who have to process the spam but to many Internet users who pay long distance charges to download their incoming mail.

The bills died on adjournment after the House Commerce Committee decided the divisive issue needed more study.

Several states, including Nevada, California and Washington, have adopted laws making it illegal for spammers to use false return addresses. And more proposals are expected at the state level when legislatures return in January.

2000 (March) - Interview in BizJournals Phoenix

By J. Craig Anderson – Mar 26, 2000, 10:00pm MST Updated Mar 26, 2000, 10:00pm MST - Source : [HW005P][GDrive]

American Computer Group: With one foot in the technology world and the other in marketing, ACG is one of the direct marketing industry's most advanced computer service bureaus.

The company provides real-time contact list management and analysis services over the Internet to direct mail marketers and telemarketers.

ACG founder Rodney Joffe has been an innovator in the use of information technology for marketing purposes -- he holds patents in both the networking and marketing fields.

Chat with Rodney Joffe, founder and chairman

Greatest strength: "Innovation. We are the leading service bureau from a technology point of view in this field."

Although many competitors have crossed over to the Internet from the old-fashioned methods of data processing in the past six months, Joffe said his company made the switch five years ago.

Biggest obstacle: "The fact that we're in Arizona. Arizona has never been accepted as an innovator in any particular field. People from outside (the state) don't realize how big and technologically advanced Phoenix is.

"People are surprised to learn that there's a whole leading-edge world in Phoenix. They think we're all living out in the sticks."

Biggest mistake: Moving to metro Phoenix in 1994. Joffe moved the 17-year-old ACG to Tempe from a Los Angeles suburb after an earthquake nearly destroyed his home and business. Although he is safe from natural disasters, Joffe said it is more difficult to attract new business.

"You aren't taken seriously in the technology world if you're from Arizona. The move was almost catastrophic for us."

Key to financial success: "Having a complete understanding of our true costs and being able to model our pricing based on that.

"We know absolutely what everything costs every step of the way."

How technology improves business: "We are a technology-driven company. We've even spawned a couple of patents."

Joffe said 40 percent of his staff is made up of programmers.

ACG uses technology to communicate and transfer data -- unlike the old days when contact lists were stored on magnetic tape and shipped by mail

"We survive on technology."

2020 (Feb 20) - Rodney Joffe Named a 2020 Cybersecurity Professional of the Year by the Cybersecurity Excellence Awards

https://www.home.neustar/blog/rodney-joffe-named-2020-cybersecurity-professional-of-year

by Miranda Joseph

We’re excited to announce that Rodney Joffe, Neustar Security CTO, SVP and Fellow and Chairman of the Neustar International Security Council, was named Cybersecurity Professional of the Year at the 2020 Cybersecurity Excellence Awards! Hosted by Cybersecurity Insiders, the Cybersecurity Excellence Awards honors individuals and companies that demonstrate excellence, innovation and leadership in information security.

Rodney was recognized for his work as a cybersecurity pioneer, his technical expertise, and his dedication to driving the field of cybersecurity forward. This award marks the third year in a row that Rodney has been recognized for his contributions to information security, after SC Media UK presented him with the ‘Outstanding Contribution to Cyber Security’ award in 2019 and winning the ‘Personal Contribution to IT Security’ category at the 2018 Computing Security Awards.

Anyone who has worked with Rodney here at Neustar will tell you how well-deserved this honor is. After all, Rodney was the architect for the development of Neustar Security’s DNS Shield and has been instrumental in building our security capabilities. Along with his work for Neustar, he has served as a cybersecurity advisor to the White House, sat on the U.S. government’s cybersecurity intelligence panel and has led a number of cyber working groups and investigations into national and international cyber-attacks and viruses. He is one of the first civilians to receive the FBI Director’s Award for outstanding cyber investigating, due to his role in uncovering and taking down the Butterfly Botnet. He is regularly called upon to assist federal authorities with investigating and protecting against cybercrime and cyberterrorist activities, and recently received the Mary Litynski Lifetime Achievement Award from M3AAWG, the global Messaging, Malware and Mobile Anti-Abuse Working Group, for his work in fighting text spam, malware and DDoS attacks.

Please join us in celebrating Rodney’s most recent accolade and the recognition Neustar continues to receive for our hard work in protecting clients with innovative and resilient security solutions.

Neustar's Rodney Joffe, TCS' Maurice Tose Extend FCC Advisory Council Terms

Neel Mehta June 16, 2015 News

Rodney Joffe

Neustar Senior Vice President and Fellow Rodney Joffe has been reappointed to a third term on the Federal Communications Commission's Communications, Security, Reliability and Interoperability Council.

Joffe will assist in work on the recommendations of communication security, reliability and interoperability best practices to the FCC, Neustar said Tuesday.

Maurice Tose

"Since the early 1990s, Rodney has recognized the inherent danger that can arise from Internet misuse and he has devoted himself and his resources to making it a safer place for all of us," said Lisa Hook, Neustar president and CEO.

TeleCommunication Systems CEO Maurice Tose has also been appointed to serve a fourth term on the council ending in 2017.

TCS said Tuesday Tose would help the council promote the 9-1-1 service, focus on network and mobile device security, protect communications networks and deliver alerts to the public.

Dr. William Karesh is the Executive Vice President for Health and Policy of EcoHealth Alliance, President of the World Organization for Animal Health (OIE) Working Group on Wildlife and Chair of the International Union for the Conservation of Nature (IUCN) Species Survival Commission's Wildlife Health Specialist Group. He serves as project liaison for the USAID Emerging Pandemic Threats PREDICT-2 program (a $140M effort to prevent infectious diseases in 30 countries) and is a member of World Health Organization's IHR Roster of Experts. In 2003, he coined the term "One Health" to describe the interdependence of healthy ecosystems, animals and people. In addition to his work in the private non-profit sector, Dr. Karesh has also worked for the USDA, US DOD and DOI. He served as a consultant for the Food and Agriculture Organization of the U.N., and is currently one of four members of the Steering Committee of OFFLU (OIE-FAO Network of Expertise for Influenzas), Dr. Karesh has led projects and programs in over 45 countries, has published over 180 scientific papers and book chapters, and written for broader audience publications such as Foreign Affairs and The Huffington Post.

One Health

From Wikipedia, the free encyclopedia

Jump to navigationJump to search

One Health is at the intersection of human health, animal health, and environmental health.

One Health is "the collaborative efforts of multiple disciplines working locally, nationally, and globally, to attain optimal health for people, animals and our environment", as defined by the One Health Initiative Task Force (OHITF).[1]

History[edit]

The recognition that environmental factors can impact human health can be traced as far back as to the Greek physician Hippocrates (c. 460 BCE – c. 370 BCE) in his text "On Airs, Waters, and Places".[2] He promoted the concept that public health depended on a clean environment.[3] In the mid-1800s, Rudolf Virchow, a physician, recognized the link between animal and human medicine, came up with the term zoonosis to describe a disease that can be passed from animals to humans, and actively advocated for veterinary medical education.[4] The founding of the Veterinary Public Health Division at the Centers for Disease Control and Prevention (CDC) in 1947 by James H. Steele, a veterinarian trained in public health, contributed to the understanding of how diseases are spread between animals and humans, or the epidemiology of zoonotic diseases.[4] Calvin Schwabe, another veterinarian trained in public health, coined the term One Medicine in a veterinary medical textbook in 1964, which reflects the similarities between animal and human medicine and stresses the importance of collaboration between veterinarians and physicians to help solve global health problems.[4] **"One Health" was first mentioned in a story about Ebola hemorrhagic fever on April 7, 2003, when Rick Weiss of the Washington Post quoted William Karesh as saying, "Human or livestock or wildlife health can't be discussed in isolation anymore. There is just one health."**[5] In 2004, The Wildlife Conservation Society held a conference at Rockefeller University in New York called One World, One Health, out of which the twelve Manhattan Principles were created.[6][7] These principles highlighted links between humans, animals, and the environment, how these links are integral to understanding disease dynamics, and the importance of interdisciplinary approaches to prevention, education, investment, and policy development.[7]

2021-02-08-findagrave-com-karl-karesh-1912-1997.pdf

Karl Karesh, the retired men's clothing store owner who was known as "Mr. King Street," died May 21, 1997 in a local hospital. He was 85.

Rabbi William Rosenthall, rabbi emeritus of K.K. Beth Elohim Temple, described Karesh as an "all-around wonderful citizen of Charleston. "He, how shall I say, clothed half of Charleston." Karesh and Max Krawcheck opened Karl Karesh Men's Apparel on King Street in 1946. The store later moved to 301 King St., where Karesh remained in business until his retirement in 1982. "I've said many times when Karl left King Street, it was one of the guard that you could not replace," said Henry Berlin, owner of Berlin's Clothiers. "He was a gentleman. He was a competitor of mine, but the kind of competitor that you would love to have." His son, Dr. William "Billy" Karesh, recalls working with his father in his store. "I don't think of him related to the business, though most of his life was committed to his work. I think my strongest thoughts about him have to do about his commitment to his community and to his family. It's really what mattered most to him throughout his life." "He was a remarkable man," daughter Barbara Stender said, noting that one of his favorite projects was the Christian-Jewish Council. "He was one of the founders. He always believed that there was a great friendship that could be developed between the Christian and Jewish people of Charleston." Eve Berlinsky, president of Beth Elohim Synagogue, said not only was Karesh a successful merchant but that "he was a caring volunteer. He was just a good citizen and a gentleman. He just cared about people and cared about life and lived it to the fullest."

Karesh was born in Charleston, SC, a son of Jacob L. Karesh and Mamie Ellison Karesh. He grew up on Radcliffe Street, the fifth of seven children. He attended Courtenay and Charleston high schools. He was an Air Force veteran of World War II. He served as president of the Jewish Community Center, chairman of the Charleston Zionist Chapter, president of B'nai B'rith Lodge, president of the Charleston Jewish Welfare Fund, treasurer of the Christian-Jewish Council of Charleston, treasurer and vice president of Beth Elohim Synagogue, and member of the Hebrew Orphan Society and Hebrew Benevolent Society. He was a member of the state board of the American Heart Association, president of North and South Carolina Retail Clothiers, and a member of the Charleston Chamber of Commerce Following his retirement in 1982, Karesh became involved with a real estate development group, Tremont Associates and worked as an agent with the Hamrick/Carter Inc. Real Estate Agency.

Surviving are his wife, Roslyn Furchgott Karesh; his son, of New York City, NY; two daughters, Barbara K. Stender of Charleston, SC, and Jae K. Casset of San Diego, CA; four step-sons, Dr. John M. Eisenberg of Washington, DC, Richard M. Eisenberg of Buffalo Grove, IL, William C. Eisenberg of Memphis, TN, and Jeff D. Eisenberg of Buffalo, NY; and 13 grandchildren.

13th President of Dartmouth College : **In office** (1970–1981)

Preceded by John Sloan Dickey / Succeeded by David T. McLaughlin

[...]

John George Kemeny (born **Kemény János György**; May 31, 1926[1] – December 26, 1992) was a Hungarian-born American mathematician, computer scientist, and educator best known for co-developing[2] the BASIC programming language in 1964 with Thomas E. Kurtz. Kemeny served as the 13th President of Dartmouth College from 1970 to 1981 and pioneered the use of computers in college education. Kemeny chaired the presidential commission that investigated the Three Mile Island accident in 1979.[2] According to György Marx he was one of The Martians.[3]

Early life

Born in Budapest, Hungary, into a Jewish family,[1] Kemeny attended the Rácz private primary school in Budapest and was a classmate of Nándor Balázs. In 1938 his father left for the United States alone. In 1940, he took the whole Kemeny family to the United States[1] when the adoption of the second anti-Jewish law in Hungary became imminent.[4] His grandfather, however, refused to leave and perished in the Holocaust, along with an aunt and uncle.[5] Kemeny's family settled in New York City where he attended George Washington High School. He graduated with the best results in his class three years later.[2] In 1943,[1] Kemeny entered Princeton University where he studied mathematics and philosophy, but he took a year off during his studies to work on

the Manhattan Project at Los Alamos National Laboratory, where his boss was Richard Feynman. He also worked there with John von Neumann. Returning to Princeton, Kemeny graduated with an A.B. in mathematics in 1946 after completing a senior thesis, titled "Equivalent logical systems", under the supervision of Alonzo Church.[6] He then remained at Princeton to pursue graduate studies and received a Ph.D. in mathematics in 1949 after completing a doctoral dissertation, titled "Type-theory vs. set-theory", also under the supervision of Alonzo Church.[7][2] He worked as Albert Einstein's mathematical assistant during graduate school.[1]

Career

Kemeny was appointed to the Dartmouth Mathematics Department as a full professor in 1953, at the age of 27.[1] Two years later he became chairman of the Department, and held this post until 1967. Kemeny ventured into curriculum development when he introduced Finite mathematics courses. He teamed with Gerald L. Thompson and J. Laurie Snell to write *Introduction to Finite Mathematics* (1957) for students of biology and social sciences. The Dartmouth mathematics department professors also wrote *Finite Mathematical Structures* (1959) and *Finite Mathematics with Business Applications* (1962). Other colleges and universities followed this lead and several more textbooks in *Finite Mathematics* were composed elsewhere. The topic of Markov chains was particularly popular so Kemeny teamed with J. Laurie Snell to publish *Finite Markov Chains* (1960) to provide an introductory college textbook. Considering the advances using potential theory obtained by G. A. Hunt, they wrote *Denumerable Markov Chains* in 1966.[8] This textbook, suitable for advanced seminars,[9] was followed by a second edition in 1976 when an additional chapter on random fields by David Griffeath was included.

Kemeny and Kurtz were pioneers in the use of computers for ordinary people. After early experiments with the LGP-30, they invented the BASIC programming language in 1964, as well as one of the world's first time-sharing systems, the Dartmouth Time-Sharing System (DTSS). In 1974, the American Federation of Information Processing Societies gave an award to Kemeny and Kurtz at the National Computer Conference for their work on BASIC and time-sharing.[10] BASIC was the language used in most software written during the rise of the Apple II, the Commodore, the TRS-80, and the IBM PCs throughout the 80s.

Kemeny was president of Dartmouth from 1970 to 1981, and continued to teach undergraduate courses and to do research and publish papers during his time as president. He presided over the coeducation of Dartmouth in 1972. He also instituted the "Dartmouth Plan" of year-round operations, thereby allowing more students without more buildings. During his administration, Dartmouth became more proactive in recruiting and retaining minority students[2] and revived its founding commitment to provide education for American Indians. Kemeny made Dartmouth a pioneer in student use of computers, equating computer literacy with reading literacy. In 1982 he returned to teaching full-time.

In 1983, Kemeny and Kurtz co-founded a company called True BASIC, Inc. to market True BASIC, an updated version of the language.

Death

Commemorative plaque to John George Kemeny. It is affixed to the wall of his former domicile.

John Kemeny died at the age of 66, the result of heart failure in Lebanon, New Hampshire[2] on December 26, 1992.[4] He had lived in Etna, near the Dartmouth Campus.

Two Times Journal, Vineland, N. J., Friday, July 15, 1949

Atomic Age Demands Strong World Government, Kemeny Tells Vineland Kiwanis Club

"The harnessing of atomic power had very serious historical implications," stated Dr. John G. Kemeny, assistant to Dr. Albert Einstein and chairman of the Princeton University chapter of the United World Federalists, at a meeting of the Vineland Kiwanis Club held last night at the Woman's Club.

Dr. Kemeny, a former member of the Atomic Bomb Project at Los Alamos, added, "Those who would go on overlooking these implications were the real dreamers of the time. Reality demands that we build political and social institutions adequate to cope with the scientific advances of our day."

"War, always morally wrong, has now become a threat to the physical existence and biological structure of every man, woman and child in the world," he emphasized.

Outlining the United World Federalists plans, Dr. Kemeny explained that the organization was started in February 1947 to strengthen the United Nations in the establishment and maintenance of peace through a world government. The group now numbers 47,000 members throughout the nation.

Strong World Govt. Urged

He urged the fundamental objective of the U.S. foreign policy to be the transformation of the United Nations into a world federation with powers clearly defined and limited to security matters. All nations would, he explained, maintain complete freedom to develop their internal political, religious, and economic systems as they chose.

"What about Russia?" Dr. Kemeny answered, "Faced by a world organized not only militarily but economically and morally, Russia could not stand alone long. Not daring to risk atomic retaliation and no longer wishing to be isolated, she would accept the necessary security checks and the way to peace would again be clear."

The speaker, who was obtained by Edward Mennies, a member of the UWF, was introduced by William G. Crossley, vice president and program chairman. John O. Milstead, past president, thanked the guest.

Samuel C. Sabul, president of the club appointed Silvio (Cy) Marcacci to the public relations committee. A report on the tuna fishing trip taken by the members was given at the meeting by Salvator Falsetta.

Guests ateding the meeting were Howard Dudley, of Millville; Stephen D. Wiley and Ann Wood, world federalists, of Morristown and Boston, respectively; Edward Mennies, and Victor Fischi, of Philadelphia.

The Vinelander
CLOTHES OF QUALITY

The special prize winner for the evening was Samuel Sabul. The prize was awarded by Dr. Lawrence R. Winchell and John Reisenwitz.

The birthdays of Duncan (Tim) Grant and Burt Dowler Sr. were celebrated.

A moment of silent prayer was observed in honor of Edward Vanaman, a member of the local chapter, who died this week. The invocation was pronounced by Rev. Calvin C. Felton, pastor of the Pilgrim Congregational Church.

Russia Won't Think Of War For 10 Years Yet, Says Gen. Smith

Philadelphia, July 15 (AP)— Gen. Walter Bedell Smith, former U. S. Ambassador to Russia, says the Soviet Union is hardly likely to consider herself ready for war with the West for at least 10 years.

He made the observation last night in a talk to 350 students and faculty members at the University of Pennsylvania.

The soldier-diplomat, now in command of the First Army, reiterated his previous observation that the outlook for the immediate future was generally for a period of "friction, disputes, and tension" between the two countries.

Gen. Smith said that the area comprising Turkey, Iran and the Middle East is now the "Achilles' heel" of Russian military planning, and that pressure may be expected to subdue these areas in the near future.

Times Journal, Vineland, N. J., Tuesday, August 16, 1949

Jewish War Vets Discuss Move For World Government

"The What, Why, and How of World Government" was discussed last night at the open meeting of the Memorial Post No. 601, U.S. Jewish War Veterans, by members of the World Government Caravan, touring New Jersey this summer.

Research assistant of Dr. Albert Einstein, of Princeton University, Dr. John Kemeny presented the "Why" of world government. Dr. Kemeny, who worked on the Los Alamos atomic bomb project, described what World War III would be like, contrasting this with the possibilities of peaceful applications of atomic energy. He pointed out that the single problem of the control of the atomic bomb cannot be solved short of World Government.

Miss Ann Wood, of Smith College, told the "What" of the argument. She said the caravan represented the United World Federalists, an organization dedicated to the task of strengthening the United Nations into a World Federation with powers limited but adequate to maintain peace. She outlined points considered necessary in the UN: control of the atomic bomb, limitation of armaments, international police force, abolishing the veto, a democratic system of representation, and a world court which can apply world laws directly to individuals.

The progress made by the United World Federalists in two and a half years of its existence were stressed by Stephen Wiley, a Princeton University junior, majoring in political science. He stated that the organization has grown to 47,000 members. Twenty-two states have passed world government resolutions, he declared.

Following the program, plans were made by the post members for a dinner-dance to be held Oct. 3. Commander Bernard Selden announced that a television set will be awarded that evening. Tickets for the occasion have already been placed on sale.

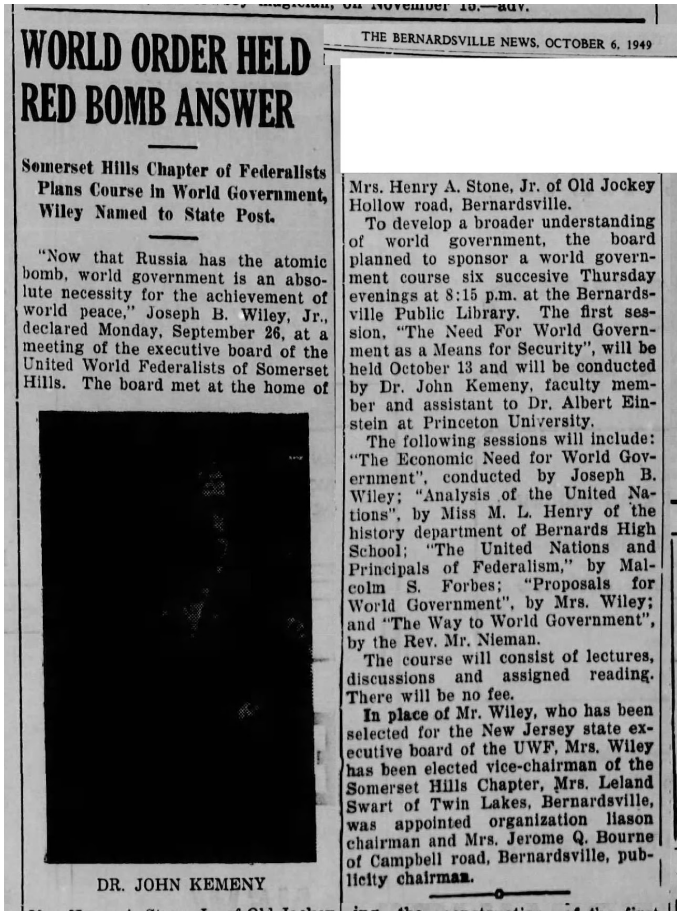
Full newspaper page : [HN016D][GDrive]



THE BERNARDSVILLE NEWS, OCTOBER 6, 1949

WORLD ORDER HELD RED BOMB ANSWER

Somerset Hills Chapter of Federalists Plans Course in World Government, Wiley Named to State Post.

"Now that Russia has the atomic bomb, world government is an absolute necessity for the achievement of world peace," Joseph B. Wiley, Jr., declared Monday, September 26, at a meeting of the executive board of the United World Federalists of Somerset Hills. The board met at the home of Mrs. Henry A. Stone, Jr. of Old Jockey Hollow road, Bernardsville.

DR. JOHN KEMENY

To develop a broader understanding of world government, the board planned to sponsor a world government course six succesive Thursday evenings at 8:15 p.m. at the Bernardsville Public Library. The first session, "The Need For World Government as a Means for Security", will be held October 13 and will be conducted by Dr. John Kemeny, faculty member and assistant to Dr. Albert Einstein at Princeton University.

The following sessions will include: "The Economic Need for World Government", conducted by Joseph B. Wiley; "Analysis of the United Nations", by Miss M. L. Henry of the history department of Bernards High School; "The United Nations and Principals of Federalism," by Malcolm S. Forbes; "Proposals for World Government", by Mrs. Wiley; and "The Way to World Government", by the Rev. Mr. Nieman.

The course will consist of lectures, discussions and assigned reading. There will be no fee.

In place of Mr. Wiley, who has been selected for the New Jersey state executive board of the UWF, Mrs. Wiley has been elected vice-chairman of the Somerset Hills Chapter, Mrs. Leland Swart of Twin Lakes, Bernardsville, was appointed organization liason chairman and Mrs. Jerome Q. Bourne of Campbell road, Bernardsville, publicity chairman.

SECOND THIRD

Bethlehem — Easton — Northampton County

FEDERALIST PARLEY — Dr. John B. Kemeny (seated right), assistant to Albert Einstein in the Institute of Advanced Study, Princeton university, is shown with Charles M. Butterworth (left), chairman, and David Caulkins, vice chairman of Lehigh university chapter, United World Federalists, at a rally Monday night in Packard auditorium, on the Lehigh campus.

Einstein Aide Urges World Government

The policy of world government was advocated by Dr. John Kemeny of Princeton university Monday night in Packard auditorium on the Lehigh university campus.

The speaker, assistant to Dr. Albert Einstein in research at the Institute for Advanced Study, told the assemblage that "great thinkers of the world have given thought to a world union for many years, but this program was only conceived as a good idea. Now these thinkers are convinced it is an immediate necessity."

Dr. Kemeny, introduced by Charles M. Butterwork, president of the United World Federalists of the Lehigh chapter, said "it is comforting to know that the same belief exists among those in prominent positions in the industrial, political and economic world."

A member of the unit which developed the atom bomb at Los Alamos, N. M., Dr. Kemeny explained that the United Nations would be benefitted by a world government. His policy, he pointed out, would be to limit power to international questions, with the countries to settle their own internal difficulties.

Butterworth, program chairman, and David Caulkins, vice chairman, discussed the purposes and beliefs of the federalists.

1965 (Sep 25) - Home computers

Full newspaper page : [HN016J][GDrive]

RUTLAND DAILY HERALD, SATURDAY MORNING, SEPTEMBER 25, 1965. 9

Home Computers Soon?

Dartmouth Professor, at Science Convention, Makes Prediction.

By WM. BURKE MILLER

MANCHESTER — (Special)— Within 50 or even 25 years some sort of computer will be standard home equipment, predicted Dr. John G. Kemeny of Dartmouth to the New England regional conference of the National Science Teachers Association Friday.

He stated that within 10 years every high school in the country will have some sort of computing equipment.

A research assistant for Dr. Albert Einstein at Princeton in 1948 and 1949, Dr. Kemeny is now chairman of the Mathematics Department and professor of philosophy at Dartmouth College in Hanover, N.H.

To show his audience of more than 375 science teachers that this was no idle statement, he described for them what is now going on at Dartmouth.

Our present computer is used by 30 students simultaneously for serious scientific purposes. Already we are planning one that will take care of 250 students, and its cost will be one quarter of the present one," he declared.

"The industrial revolution eased man's existence yet increased his ability to produce. And so it will be that computers, properly used, can vastly extend man's mental powers and accomplishments."

Only one problem appeared, Dr. Kemeny went on.

"It will be as difficult for a computer to decipher handwriting as man finds it," he said. Typing, not professional work but two finger hunt-and-punch, will suffice, he added.

The rainy day did not interfere too much with the second day of the three-day meeting. A poolside buffet luncheon was cancelled; some planned golf foursomes were called off and the stargazing from Burr & Burton observatory had to be cancelled.

Most sessions were well-attended throughout the afternoon. The exhibition hall had many browsing about longer than usual. Color movies on "Challenge of the Oceans," and "Viruses," were shown in the convention hall.

Loop projectors were on display next to the lobby at the Equinox House. Many had read and heard about them but said this was the first time they had seen or been able to operate them.

Other afternoon activities were a discussion of junior high school science, by Prof. Thomas Sachs of the University of Vermont.

Among the guests was Mrs. Westphalie G. Villahermosa, technical assistant of the National Science Development Board of the Philippines. She has been at Putney with the Experiment for International Living.

The conference will continue for most of Saturday.

At 9:45 a.m. there will be five concurrent sessions. These will be on a Princeton secondary school science project; Minnesota mathematics and science teaching project; AAAS Commission on Science Education; elementary school science project, University of Illinois, and a public school introduction to physical sciences.

From 11 a.m. to noon there will be a panel on in-service science education with Dr. Thomas Aylesworth and Ray Broekel of Wesleyan University, and Hiram R. Haggett, NASA educational program officer.

Following lunch, concurrent sessions will resume until 2:15 p.m. Exhibits will close at 2:30 p.m. and the conference will be ended.

Officers of the Vermont Mathematic and Science Teachers Association, who were sponsors of the event are John Emerson, president, Bradford Academy science department; Mrs. Barbara Ragle, vice president, elementary science teacher, Norwich, and Arthur Scott, secretary and treasurer, secondary mathematics teacher at Champlain Union High School, Hinesburg.

Full newspaper page : [HN0169][GDrive]

CONTRACT SIGNED

1967-10-24-asbury-park-press-nj-pg-4-clip-monmouth-college-data-processing

Monmouth College Expands Data Processing Facilities

WEST LONG BRANCH — Students and faculty at Monmouth College will soon have access to the most advanced facilities in electronic data processing.

After intensive investigation into the academic applications of data processing, the college has signed a contract to tie in with the remote - access, time-shared facility operated at Teaneck by the General Electric Co.

By taking this step, Monmouth College has become one of the few colleges in New Jersey to provide this service for its students and staff and places itself among the relatively few colleges and universities in the United States with time-shared data processing on its campus.

Initially the installation at Monmouth College will be limited to teletypewriters in a computer center located in Edison Science Hall. Provision for expansion of the computer center includes addition of punched card transmission equipment and the installation of remote teletypewriters elsewhere on the campus as needed.

Besides the availability of the FORTRAN and ALGOL languages, one of the appeals of the facility at Monmouth College will be the inclusion of a language called BASIC, by which users of the equipment will be able to communicate. Developed by Professor John Kemeny of Dartmouth College, BASIC is an easy - to - learn, useful language for data processing communication.

It is applicable to both scientific and business education, and therefore is ideally suited to the college environment. Communication via teletypewriter directly with the GE 265 computer will permit the ultimate in data processing experience for the student.

Monmouth College has taken a step forward in providing this capability. Any student entering a technical or business field will have the advantage of previous knowledge of what electronic data processing can accomplish, and will have had experience with its use. It is expected that high schools will be teaching data processing soon. Monmouth College education majors may graduate qualified to teach data processing at the high school level.

Members of the Monmouth College Committee who studied the need and use of data processing were Everett W. Holt, dean of the faculty; Roscoe E. Labosier, business manager; and Dr. D. Robert Teeters, associate professor of physics.

Dr. William G. Van Note (right), president of Monmouth College, signs a contract for the college to tie in with the remote-access, time-shared facility operated at Teaneck by the General Electric Co. Everett W. Holt (left), dean of the faculty at the college, and Eugene W. Dooley, sales representative for G.E., look on.

New Computer Vastly Increases Dartmouth's Information System

HANOVER, N.H. — Purchase of a new Honeywell 66-40 computer to accommodate the continuing growth in computing among Dartmouth College students, faculty, administration, and educational networks encompassing other schools was announced by John G. Kemeny, president of the college and co-developer of the Dartmouth Time-Sharing System.

The financing of new fourth generation hardware was made possible, in part, by a second $500,000 gift from Peter and Evelyn Kiewit, in whose honor the college's computation center is named. The first $500,000 gift from Kiewit, a member of the Dartmouth Class of 1922 and president of the international construction firm of Peter Kiewit Sons & Co. of Omaha, Neb., helped to underwrite construction of the Kiewit Computation Center, dedicated in 1966 to provide Dartmouth with a physical base for its pioneering work in educational time-sharing computing.

The new Honeywell 66-40 — faster, more versatile and with larger storage and operating capacity than the Honeywell 635 it will replace — is scheduled to be installed prior to the winter term, early in January. Initially it will be run concurrently with the 635 and be tested in that configuration. Only after the new computer has been thoroughly tested will the old equipment be removed, in order to maintain uninterrupted computer service for its thousands of users.

Comparative simulations inducate that response time on the 66-40 system will improve by 10 to 40 per cent while storage and operational capacity will be enlarged by 30 per cent. The new machine will also provide capacity for growth and innovation during the next decade. The new configuration has two of every essential component, thereby permitting continued service while any part is being repaired or used for experimental development.

For several years now, an average of 85 to 90 per cent of the undergraduates at Dartmouth, now totalling 4,000 men and women, have gained direct computing experience on the Dartmouth Time-Sharing System (DTSS). The college's computer facilities also receive heavy use from graduate students at the Amos Tuck School of Business Administration, the Thayer School of Engineering and even the Dartmouth Medical School.

Faculty in virtually all disciplines from anthropology to zoology are making increasing use of the computer for their own research as well as utilizing it as a learning and functional tool for their students. Similarly, under the impetus of Dr. Kemeny, the College has developed a sophisticated management-information program, FIND, to assist in advance planning as well as data storage, retrieval and analysis.

In announcing the purchase of the Honeywell 66-40, Dr. Kemeny declared: "We have realized for some time that a new computer was going to be a necessity if we were to maintain the excellent computer service which has become part of the modern Dartmouth education. With the arrival of the new equipment, we can continue to grow in computer technology, while at the same time improving computing efficiency for the entire Dartmouth community."

He noted that extraordinary burdens had been placed on the 10-year old 635 machine because of the increase since 1972 in the number of undergraduates at Dartmouth from 3,000 to 4,000, following the advent of coeducation, the mounting use of the computer by individual students, year-round operation of the college and the greater administrative use of the computer.

"The new computer," he said, "will give us the increased capacity we presently need as well as additional capacity for future growth."

Commenting on the new acquisition, John S. McGeachie, director of the Kiewit Computation Center, added: "This new installation will ensure a continuation of the standard of excellence for which computing at Dartmouth is nationally recognized. I certainly look forward to its arrival.

"As an educational tool, the computer has come of age, and is an integral part of the academic life of the institution. The trustees' vote to purchase a new computer reinforces Dartmouth's continuing commitment to academic excellence and leadership in computing."

There are more than 400 computer terminals at strategic locations around the campus for student and faculty use. With the 635, more than 150 persons could use the computer simultaneously, each with his or her own program or project. The new equipment is expected to provide far better service to approximately the same number of simultaneous users.

The decision to purchase the new equipment was approved by the Board of Trustees at their fall meeting on the recommendations of the director of the computing center and two college-wide

Dartmouth makes most of computer

United Press International

HANOVER, N.H. — On most college campuses students head for the library to work on assignments. At Dartmouth they are apt to head for the computer.

"We feel we're just as important a part of the education program as the library," said Thomas Byrne, assistant director for administration at the Kiewit Computation Center.

More than 90 per cent of the 4,000 Dartmouth students make use of the computer and more than 150 courses use it as an integral part of the course.

"One man computerized some lectures so they were self-teaching. This gave him two hours to lecture about things he never had time for before," Byrne said.

Courses involving complex computations can give more realistic problems. One student did tabulations on how the suburbs voted in 1972, finding on most issues they voted conservatively.

"The paper he did for one course would have gotten him a Ph D in years past" because it would have taken that much effort to get statistics together and analyze them, Byrne said.

Widespread use of Dartmouth's one computer is possible because of the work a decade ago by two Dartmouth professors — John G. Kemeny, now president of the college, and Thomas E. Kurtz, now director of the Kiewit Center.

They did two things that have helped revolutionize the computer industry worldwide.

They worked out a time-sharing program which allows many people to use a large central computer at the same time, while it seems to each user he has exclusive use of the system.

And they invented a computer language, called Basic, which lets computer users give commands in simple English instead of complex mathematical formulas.

"Massachusetts Institute of Technology had done some work on timesharing. We tried to do a less expensive version," Byrne said.

Kemeny and Kurtz felt one reason it was impractical to introduce students to the computer was that the language was too complex.

"They tried to design a language using simple English words to transmit commands to the computer. Basic turned out to be so simple a student could learn it in two hours," he said.

It now is the most popular language worldwide for use in timesharing programs. It is powerful because of its range of commands. With it, for example, you can edit texts, work in graphics and retrieve information.

Basic uses self-explanatory word commands such as "stop, run, print, end, list, read, write, scratch, go to, sort." Another important word is "let," as in mathematical formulas like "let X equal Y."

General Electric picked up the timesharing program, copied it around the country, and was so pleased it entered into a three-year research project with Dartmouth and gave the school a new $2.5 million computer.

"The Dartmouth time sharing system was raised in a college environment so our applications are peculiarly suited to a college environment," Byrne said. It has been leased to prep schools around New England, to several major companies, and to the U.S. Naval Academy at Annapolis.

The system has a library of 800 programs which can do anything from help design bridges to send out town water bills, to play word games with children—a good way to get them interested in using a tool which can give help in almost any field.

"We assume a great number of Dartmouth graduates will get into positions where they have to make decisions. With the world as it is, these decisons likely will involve information stored in a computer," Byrne said.

"We think it's essential the students understand the capabilities and limitations of the computer," he said.

Computer lingo at Dartmouth

HANOVER, N.H. — A grant of $31,300 has been awarded to Dartmouth College by the National Science Foundation to support development of a national standard syntax for graphical operations in the computer language BASIC, according to Prof. Arthur Luehrmann, assistant director of the Kiewit Computation Center.

The project, which is funded from Jan. 15, 1975 to Jan. 15, 1976, will add graphical statements to BASIC. A national panel of experts from universities and industry will assist in the program.

The project actually began in October 1974, under the development of Luehrmann, when a national panel held a conference at Dartmouth's Minary Conference Center to discuss the needs and prospects of such a language development. Additional support in the amount of $7,400 has been received from the National Bureau of Standards, California Computer Products Inc., Hewlett Packard Inc., UNIVAC, and Tektronix.

According to Luehrmann, "Some of the most compelling examples of education computer use are ones that involve graphics. Yet, it is very difficult to transport these programs to other institutions because there are no standards for writing graphical programs. We hope to change the situation so that BASIC programmers will have a standard way to write graphical programs that can be exchanged easily."

The language BASIC was developed at Dartmouth in the early 1960s by President John G. Kemeny and mathematics professor Thomas E. Kurtz, director of the Kiewit Computation Center. It has since gained acceptance as one of the world's major computer languages.

The panel working on this project is one of national stature and includes, in addition to Luehrmann, Professors Stephen J. Garland and Larry R. Harris of the mathematics department at Dartmouth, and representatives from several other institutions.

The project welcomes correspondence from people who would like to influence its outcome or be kept informed of its progress.

Is U.S. becoming nation of computer illiterates?

© 1979 N.Y. Times News Service

NEW YORK — If "Why can't Johnny read and write?" has been the education story of the 1970s, then the story of the 1980s might well be "Why can't Johnny use a computer?"

With computers revolutionizing the way Americans pay their bills, shop, and make their major business and political decisions, many educators find a lack of understanding of the power and limitations of these machines and believe that America is a nation of computer illiterates.

John Kemeny, president of Dartmouth College and one of the nation's leading authorities on computers, believes the nation's ability to nurture a "computer literacy" is a fundamental issue of the next decade.

Currently, slightly under 40 percent of the nation's 11.3 million college students graduate with some basic knowledge of computers, according to figures compiled by Prof. John Hamblen, chairman of the computer science department at the University of Missouri at Rolla.

And only 10 to 20 percent of the faculty members know enough about computers to use them in their courses.

"I have run into a great many people in industry whose businesses depend on computers," Kemeny said, "and they simply don't even know what questions to ask of their computer experts. That's a dangerous situation."

To give as many students as possible an opportunity for computer experience, Kemeny believes every college and university should make computer services as readily available to their students as books on their library shelves.

That is the philosophy he has used in establishing Dartmouth as a national leader in the use of computers in education.

Computers have become so pervasive on campus that few faculty members or students consider them special any more.

"In many institutions," said Thomas Kurtz, a professor of mathematics who has worked closely with Kemeny to develop the services at Dartmouth, "the computer is an object of mystery surrounded by bureaucrats who are there to protect the knowledge of the computer experts."

Students must ask the experts to run their programs, Kurtz noted, and often hardly touch the machinery. They are left with the notion of the computer as "some sort of a God that hangs over their lives. Students at Dartmouth don't have to see anybody to get on the computer. It's no mystery."

More than 300 terminals, some like large electric typewriters and some like typewriters hooked up to a television screen, are in buildings around the campus. Any student can use one simply by typing in his student number.

Computers are used in nearly 200 courses, according to one recent survey. Even students who manage to avoid those courses often become so curious about the terminals that they learn to use them on their own.

"Part of being at Dartmouth is becoming comfortable with the computer," said Fran L'Esperance, a senior from Engiewood, N. J. "You can't help but learn something about it."

Indeed, in the last few years, more than 90 percent of the college's graduates had some computer experience while at Dartmouth. This figure was up to 96 percent last year, college surveys showed. The vast majority of them can write at least a simple program.

Few institutions offer such services to so many students, but the use of computers has been growing steadily on campuses for more than a decade.

In fact, Hamblen's study indicates that colleges and universities have now spent more than $1 billion on computing activities.

"The computer has pervaded practically every discipline, in both instruction and research," Hamblen said. "And it's really just beginning in instruction."

Examples include the following:

— A computer in a simulation game course on urban issues at the University of Southern California gives students playing the roles of city officials, developers and pressure groups information they need to make decisions on such issues as energy conservation, highway construction and capital budget planning.

The programs, covering more than 40 issues, have been used in 200 universities here and abroad.

— At Dartmouth, music students use a computer that reproduces dozens of musical sounds ranging from the human voice, piano and brass to electronic music only a computer can play. A student who writes music for a quartet, for example, can hear how it sounds on a computer before it is performed by live musicians.

— Also at Dartmouth, a special program known as IMPRESS provides sociology students with a vast resource of raw statistics, including census figures on sex, race, income and marital status, and political election results.

"The students go directly to the information on which their textbooks are based, and they question it," explained Gerald Levine, a sociologist.

— At Babson College, a business-management school in Wellesley, Mass., Prof. Jack Stamm programs into a computer background information on companies and unions involved in collective-bargaining disputes.

In simulating labor negotiations, graduate students must ask the computer for information to help them formulate bargaining positions.

— Physics students at Dartmouth study Newton's Laws by planning a voyage to the moon. Without a computer, such an assignment would involve tens of thousands of calculations.

Students program the computer to do the calculations by "teaching" it Newton's Laws, a process that requires the students to understand the laws.

These and other computer uses are going on at about 2,100 colleges and universities, according to information Hamblen has compiled, but 1.3 million students at 1,000 colleges have no access to computers.

For Kemeny the issue goes beyond a listing of the kinds of courses that use computers. It is a question of attitude.

He tells the story about a doctoral candidate at one institution with excellent computer facilities who was prevented from finishing his thesis for six months.

The student needed $500 worth of computer time and the university would not give it to him.

"Compare it to the library," Kemeny said. "For that student, anything he would have needed in the library to finish his thesis would have been available. And if it wasn't in the library, they would have paid interlibrary loan fees to get him the books or the journals to finish his thesis."

It is one illustration that convinces Kemeny that colleges have a long way to go in both available services and in philosophy in the effort to bring up a computer-educated generation.

"There really are very few schools that have adopted computer literacy as a major institutional goal," he said.

John G. Kemeny; Creator of BASIC Computer Language

From Times Staff and Wire Reports

LEBANON, N.H.—John G. Kemeny, a former president of Dartmouth College, co-creator of the widely used computer language BASIC and a scientist whose involvement in nuclear energy began with the Manhattan Project and extended through an investigation of the near-disaster at Three Mile Island, is dead.

The distinguished mathematician died Saturday, apparently of a heart attack, a Dartmouth spokesman said. He was 66.

Kemeny was a research assistant to Albert Einstein while studying at Princeton University, where he received his doctorate when he was only 23.

Earlier, as an Army soldier during World War II, he worked as an assistant in the theoretical division of the Los Alamos nuclear project that developed the atomic bomb.

Kemeny served as Dartmouth's 13th president from 1970 to 1981, when he stepped down to return to teaching. He guided the university through a series of changes, including the admission of women in 1972, and recommitted the school to its founding mission of educating American Indians.

His tenure also was marked by a growing conservative sentiment that came to dominate the New England campus. When he stepped down in 1981, Kemeny warned of the intolerance he saw within that movement.

Kemeny "pushed the fields of mathematics and computing to new heights, just as he raised the stature of Dartmouth during a decade of change in the 1970s," Dartmouth President James Freedman said.

Kemeny was born in Budapest, Hungary, and immigrated to the United States in 1940. He became a U.S. citizen in 1945 and quickly joined the Army.

He was graduated from Princeton in 1947 and earned his doctorate from the school two years later.

Kemeny and a colleague at Dartmouth, Prof. Thomas Kurtz, invented BASIC computer language in 1964. It remains a major tool in teaching computer programming.

In 1979, President Jimmy Carter named Kemeny to head a 12-member commission that investigated the accident at Three Mile Island nuclear power plant at Middletown, Pa. The Kemeny Commission, as it came to be called, was highly critical of the nuclear power industry and its federal regulators.

Known for

On Thermonuclear War

Herman Kahn (February 15, 1922 – July 7, 1983) was a founder of the Hudson Institute and one of the preeminent futurists of the latter part of the twentieth century. He originally came to prominence as a military strategist and systems theorist while employed at the RAND Corporation. He became known for analyzing the likely consequences of nuclear war and recommending ways to improve survivability, making him one of the historical inspirations for the title character of Stanley Kubrick's classic black comedy film satire *Dr. Strangelove*.[1]

His theories contributed heavily to the development of the nuclear strategy of the United States.

Background[edit]

Kahn was born in Bayonne, New Jersey, the son of Yetta (née Koslowsky) and Abraham Kahn, a tailor.[2] His parents were Jewish immigrants from Eastern Europe. He was raised in the Bronx, then in Los Angeles following his parents' divorce.[3] Raised Jewish, he later became an atheist.[4]

Cold War theories[edit]

Kahn's major contributions were the several strategies he developed during the Cold War to contemplate "the unthinkable" – namely, nuclear warfare – by using applications of game theory. Kahn is often cited (with Pierre Wack) as a father of scenario planning.[5]

Kahn argued for deterrence and believed that if the Soviet Union believed that the United States had a second strike capability then it would offer greater deterrence, which he wrote in his paper titled "The Nature and Feasibility of War and Deterrence".[6]

The bases of his work were systems theory and game theory as applied to economics and military strategy. Kahn argued that for deterrence to succeed, the Soviet Union had to be convinced that the United States had second-strike capability in order to leave the Politburo in no doubt that even a perfectly coordinated massive attack would guarantee a measure of retaliation that would leave them devastated as well:

> At the minimum, an adequate deterrent for the United States must provide an objective basis for a Soviet calculation that would persuade them that, no matter how skillful or ingenious they were, an attack on the United States would lead to a very high risk if not certainty of large-scale destruction to Soviet civil society and military forces.[7]

Hudson Institute[edit]

In 1961, Kahn, Max Singer and Oscar Ruebhausen founded the Hudson Institute,[8] a policy research organization initially located in Croton-on-Hudson, New York, where Kahn was living at the time. Luminaries such as sociologist Daniel Bell, political philosopher Raymond Aron and novelist Ralph Ellison (author of the 1952 classic *Invisible Man*) were recruited.

The Year 2000[edit]

In 1967, Herman Kahn and Anthony J. Wiener published *The Year 2000: A Framework for Speculation on the Next Thirty-Three Years*, which included contributions from staff members of the Hudson Institute and an introduction by Daniel Bell. Table XVIII in the document[9] contains a list called "One Hundred Technical Innovations Very Likely in the Last Third of the Twentieth Century". The first ten predictions were:

1. Multiple applications of lasers.
2. Extreme high-strength structural materials.
3. New or improved superperformance fabrics.
4. New or improved materials for equipment and appliances.
5. New airborne vehicles (ground-effect vehicles, giant or supersonic jets, VTOL, STOL).
6. Extensive commercial applications of shaped-charge explosives.
7. More reliable and longer-range weather forecasting.
8. Extensive and/or intensive expansion of tropical agriculture and forestry.
9. New sources of power for fixed installations.
10. New sources of power for ground transportation.

Later years[edit]

In Kahn's view, capitalism and technology held nearly boundless potential for progress, while the colonization of space lay in the near, not the distant, future.[10] Kahn's 1976 book *The Next 200 Years*, written with William Brown and Leon Martel, presented an optimistic scenario of economic conditions in the year 2176. He also wrote a number of books extrapolating the future of the American, Japanese and Australian economies and several works on systems theory, including the well-received 1957 monograph *Techniques of System Analysis*.[11]

During the mid-1970s, when South Korea's GDP per capita was one of the lowest in the world, Kahn predicted that the country would become one of the top 10 most powerful countries in the world by the year 2000.[12]

In his last year, 1983, Kahn wrote approvingly of Ronald Reagan's political agenda in *The Coming Boom: Economic, Political, and Social* and bluntly derided Jonathan Schell's claims about the long-term effects of nuclear war. On July 7 that year, he died of a stroke, aged 61.[13]

Personal life[edit]

Herman Kahn was the son of Abraham Kahn and Yetta Kahn. His wife was Rosalie "Jane" Kahn. He and Jane had two children, David and Debbie.[14]

Cultural influence[edit]

Along with John von Neumann, Edward Teller and Wernher von Braun, Kahn was, reportedly, an inspiration for the character "Dr. Strangelove" in the eponymous film by Stanley Kubrick released in 1964.[1] It was also said that Kubrick immersed himself in Kahn's book *On Thermonuclear War*.[15] In the film, Dr. Strangelove refers to a report on the Doomsday Machine by the "BLAND Corporation". Kahn gave Kubrick the idea for the "Doomsday Machine", a device which would immediately cause the destruction of the entire planet in the event of a nuclear attack. Both the name and the concept of the weapon are drawn from the text of *On Thermonuclear War*.[16] Louis Menand observes, "In Kahn's book, the Doomsday Machine is an example of the sort of deterrent that appeals to the military mind but that is dangerously destabilizing. Since nations are not suicidal, its only use is to threaten."[16]

In *The Politics of Ecstasy*,[17] Timothy Leary suggests that Kahn had taken LSD.

Publications[edit]

Outside physics and statistics, works written by Kahn include:

Nov. 4, 1979 - Obituary, NY Times : "Peter Kiewit, 79, Builder in West; Public Works Created an Empire"

Source : [HN00ZJ][GDrive]

Peter Kiewit, a Nebraska construction executive whose $400 million dollar empire was amassed through building of tunnels, dams, highways and other public works projects that, critics charged, sometimes dragged far behind schedule at exorbitant costs to taxpayers, died Friday in Omaha. He was 79 years old.

Mr. Kiewit had been suffering from a malignant - tumor in his remaining lung. The other was removed on Sept. 21, at Omaha's Clarkson Hospital. Mr. Kiewit was released 10 days after the surgery but re - entered the hospital 10 days ago.

Mr. Kiewit, whose conservative, Middle Western manner was said to resemble that of a minister, devoted his adult life to expanding what his family, Dutch immigrants, began in 1884 as a modest masonry concern.

The enterprise — now known as Peter Kiewit Sons' Company, one of the world's largest construction concerns — was one in which Mr. Kiewit found a start as bricklayer at the age of 19. After one year at Dartmouth College, he dropped out, saying, later in life, "college was too expensive and not offering of enough results."

As the owner of The Omaha World - Herald properties — a daily newspaper, a publishing company, TV station and office buidlings and other real estate — Mr. Kiewit was perhaps the leading figure in Nebraskan social and business circles. Other Kiewit holdings include coal mines in Wyoming and Montana and a quarry in New Mexico.

He was a former board chairman of the Chicago, Rock Island and Pacific Railroads, the Northwestern Bell Telephone Company, the Omaha National Bank and the Northern Natural Gas Company. Estimates of his personal wealth ranged from $150 million to $200 million.

He maintained ranches in Nebraska, and in Wyoming, near the Big Horn Mountain range. He owned other residences in downtown Omaha and in Palm Springs, Calif.

Mr. Kiewit, a man who preferred to go unnoticed, nevertheless took a vigorous personal interest in business, crossing the nation constantly in his private plane, between his company branches and his residences. "Publicity never got us a job," he told his employes.

In one notable case, the builder was criticized in 1968 by a member of the board of directors of the Omaha power district over the the cost of a nuclear power plant at Fort Calhoun, Neb. Though the original cost estimate was $64 million, Mr. Kiewit eventually raised it to $163 million. The plant's operation date, first set for May 1, 1971, was moved back to June 1, 1973. The job went through despite the criticism.

Stressing his own problems with such things as low productivity by workers, and inflation, Mr. Kiewit finished the project in August 1973 at a cost of $172 million.

Mr. Kiewit is survived by his third wife, the former Marjorie Harkins Buchanan of Chicago, and a son, Peter Kiewit Jr., an attorney in Phoenix.

1979 (Nov 11)

Construction giant Peter Kiewit dead at 79

From News Wires

OMAHA — Peter Kiewit, a Nebraska bricklayer who built one of the world's largest construction firms, died Friday at the age of 79. Funeral arrangements were pending.

Kiewit's left lung was removed Sept. 21 at Clarkson Hospital after discovery of a malignant tumor. He was released about two weeks after the surgery, but re-entered the hospital about 10 days ago for surgery to repair a bleeding ulcer.

Kiewit started his career as a bricklayer in 1919. Today, the enterprises of Peter Kiewit Sons' Inc. are worth more than $400 million. Kiewit's company became principal owner of the Omaha World-Herald in 1962.

"Peter Kiewit will be remembered always as a construction leader, but his eminence in that field should not diminish his important Nebraska role as owner of the Omaha World-Herald," said Joe R. Seacrest, editor of the Lincoln Journal. "He brought to the World-Herald more than local ownership. He brought talent and a more moderate editorial leadership to a fine newspaper."

Kiewit was chairman of a contracting firm that spread over North America, but he kept his legal residence and his company's headquarters within two miles of the modest frame house in Omaha where he was born.

Highway builder

The construction company is one of the largest in the world and is the largest builder of Interstate highway in the United States. Since 1946, it has completed more than half a billion dollars worth of highways and superhighways.

The day Kiewit died, the company was working at more than 150 construction sites.

One of his company's trademarks was training employees for greater responsibilities. Some 370 employees own stock in the company and employees eventually will assume ownership of the firm.

Kiewit's philanthropies, already given or pledged for the next five years, total $20 million. Among his contributions was $2.5 million for the downtown Omaha education center-state office building.

Among projects on which Kiewit construction work is being done are pumping stations on the Alaska Pipeline, the Big Thompson Canyon highway reconstruction project in Colorado, the Eisenhower Tunnel in Colorado, a huge hydroelectric project in the James Bay region of northern Quebec, Canada, and subway projects in Boston, Washington, D.C., and New York City.

Kiewit companies are mining coal in Wyoming and Montana, quarrying rock in New Mexico and building tunnels through the Colorado Rocky Mountains. By 1978, Peter Kiewit Sons' become the 10th largest coal producer in the United States.

Coal mining

The company holds contracts to deliver some $4 billion worth of coal in the next 20 years.

In the corporate structure, Peter Kiewit Sons' Inc. is the parent holding company. Peter Kiewit Sons' Co. is the construction arm, with 14 regional and district offices in the United States and Canada, and is the largest of about 25 subsidiaries.

Kiewit received many honors and awards, but he said few touched him as much as a citation he received in 1968 from the Beavers, an organization of construction men.

The citation said: "Obviously, Peter Kiewit does more than build lasting monuments of masonry, concrete and steel. He also builds men and good things for a better, more meaningful world."

In 1922, Kiewit married Mary Drake, daughter of a bridge builder. They had two children, a son, Peter Kiewit Jr., now an attorney in Phoenix, Ariz., and a daughter, Mrs. Jeanne Kiewit Taylor, who died in 1953.

Mary and Peter Kiewit were divorced in 1951 and in 1952, he married Evelyn Stotts Newton, widow of one of Kiewit's early business associates in Omaha. She died in 1977 and in February 1978, Kiewit married a Chicago widow, Marjorie Harkins Buchanan.

Kiewit and Buffett shared a pilot !

Wilbert Edwin Emshoff : November 2, 1927 - July 24, 2019

Source on TributeArchive : [HL004D][GDrive]

Wilbert E. Emshoff, age 91, of Omaha, passed away on July 24, 2019. Wilbert was born in Avoca, NE on November 2, 1927 to the late John and Matilde (Koester) Emshoff. He proudly served his country in the United States Air Force and worked as a corporate pilot for Peter Kiewit and Warren Buffett. Wilbert is survived by his wife, Leora, daughters, Peggy Cox (Bill), Debbie Schug (Mark), sons, Randy Emshoff (Janet), Keith Emshoff (Terry), five grandchildren and three great grandchildren. He was preceded in death by his parents, two brothers and two sisters.

Peter Kiewit – The Story of Warren Buffett's Mentor

Source : IntelligentFanatics (2017 article) : [HW003R][GDrive]

Here is an excerpt from our new book, Intelligent Fanatics: Standing on the Shoulders of Giants 82:

Peter Kiewit Sons', Inc.

"If you set out to replicate the Kiewit company, you could put as much capital into the business as it has. You could move into corporate quarters that rival Kiewit's. You could even buy all its equipment and replicate its organizational structure. But, you would not be able to build a culture like Kiewit's. That culture is the result of the vision of an extraordinary man, carried on and moved forward by extraordinary people. You could canvass the world, recruiting the top picks from Stanford, Harvard—you name it—and you would never replicate the magic and success that is the culture of the Kiewit company."

—Warren Buffett, in *Kiewit: An Uncommon Company*

"The three best operating companies I'm aware of are Costco, Kiewit, and Glenair. There is nothing remarkable about the product or field for any of these three. But there is something remarkable about the *culture* of all three."

—Charlie Munger, in a talk to Capital Group executives

In 1951, Warren Buffett received his graduate degree from Columbia University, where he studied under Benjamin Graham. After graduation, he worked at Buffett-Falk & Company until 1954. At the time, Buffett-Falk was located on the fourth floor of the Omaha National Bank Building, suite 445. In that same building, on the tenth floor, was an intelligent fanatic named Peter Kiewit. Peter grew his family's business from the twelfth-largest contractor in Omaha to one of the largest and most respected in the entire United States.

Buffett would learn as much from Peter Kiewit and his successor, Walter Scott Jr., as he did from Benjamin Graham. Peter Kiewit also made an indelible mark on Omaha. Most people outside of Omaha are not familiar with Peter Kiewit or the outstanding company he led—Peter Kiewit Sons', Inc. (PKS).

By the 1950s, Peter Kiewit was a legend in Omaha, having constructed dozens of buildings throughout the city. Young Buffett, fresh out of Dale Carnegie's course on public speaking, took it upon himself to reach out and meet Peter Kiewit. They met in 1952, and Buffett was surprised at how nice Kiewit was, for a man of his notoriety and stature.

From that one meeting in 1952, Warren would go onto emulate Peter in terms of character, business building, and giving. Buffett says, "It's better to hang out with people better than you. Pick out associates whose behavior is better than yours and you'll drift in that direction,"1 True to this, Buffett eventually chose to partner with Kiewit, the business, on a few deals and to locate Berkshire Hathaway only a few floors away from PKS, known today as Kiewit Corporation, in Kiewit Plaza.

The connections between Berkshire Hathaway and PKS have been strong over the decades. Walter Scott Jr., who became president of PKS after Peter Kiewit's passing, had been a childhood friend of Warren. Scott has been a long-term director on Berkshire Hathaway's board. When Warren was contemplating getting a corporate jet for Berkshire, in the late 1980s, he knew Peter Kiewit had successfully utilized multiple private aircraft to move himself and employees to remote construction sites. He asked Walter Scott his opinion: "Walter, how do you justify buying a private airplane?" Walter replied, "Warren, you don't justify it. You rationalize it."2 Buffett would later state, after purchasing the $6.8 million *Indefensible* in 1989, that the jet was one of his few "guilty pleasures." He rationalized the benefit of saving his time in traveling for Berkshire Hathaway.

Berkshire Hathaway also has had multiple business transactions directly or indirectly with PKS. Take, for instance, MidAmerican Energy Company. MidAmerican Energy's predecessor, CalEnergy Company, was a majority-owned stake of PKS before Berkshire Hathaway acquired it in 2000. Additionally, again with the help of Walter Scott Jr., Warren Buffett honored Peter Kiewit's wish to keep the Omaha newspaper the *World-Herald* locally owned. Peter Kiewit's company had purchased the newspaper in 1962, for $40.48 million, with only sixteen days' notice. The business was almost acquired by Samuel I. Newhouse's New York City newspaper franchise. Residents and employees were furious that a nonlocal entity could be the owner. Kiewit said, "I figure anything as important to a city as its newspaper will be a good, sound investment."3

With mounting debt, the *World-Herald* needed an opportunity to address its long-term capital needs while maintaining local ownership. Warren Buffett stepped up in 2011, as Peter had forty-nine years earlier, and through Berkshire Hathaway acquired the *World-Herald* for $150 million. Like Kiewit, Buffett saw the *World-Herald* as a sound investment, different than most newspapers in the United States, which he would not own "at any price." He said in the press release that this newspaper "delivers solid profits and is one of the best-run newspapers in America."4

Upon Peter's death, Warren also shared his view of Peter's giving. He said, "Peter Kiewit made major deposits in society's bank . . . but his withdrawals have been few."5 Peter Kiewit gave generously while he was alive, and the majority of his net worth upon his death. With the help of the Gates Foundation, Buffett will closely follow Kiewit's major deposits in society's bank, with minimal withdrawals.r

Peter Kiewit operated in a difficult industry. BizMiner, an industry analysis provider, estimated that from 2004 to 2006 the failure rate for various contracting firms in the United States was 23.6%.6 Developers and governments are highly price sensitive. Contractors bid for projects with no knowledge of their competitor's bids. Winning really comes down to price, and there are numerous factors outside the control of the owner.

So how was it that, in the depths of the Depression—1931 to be exact—Peter Kiewit persevered and grew his father's business from $400,000 in annual revenues to a $7 billion, nationally recognized contracting firm upon his death in 1979? And how does the company maintain dominance in the United States even to this day?

We will highlight Peter Kiewit's story and how he did it. Not surprisingly, he and PKS fit the intelligent fanatic mold. We also will juxtapose PKS with two other contracting firms that did not utilize the same strategies Peter Kiewit built and did not achieve the same sustained success.

You can read Peter Kiewit's story in our latest book, Intelligent Fanatics: Standing on the Shoulders of Giants 82. Become a Member and we'll send you the eBook-Kindle version for Free. **[Join Today]** 12

[...]

Dec '17 - I thought this was a very good excerpt from a 1986 Fortune article:

Buffett especially admires how fellow Omaha businessman Peter Kiewit solved his legacy problem. Kiewit arranged his affairs so that when he died in 1979 his 40% stake in the family's enormously successful construction company was sold to employees. The proceeds from the sale then went to a charitable foundation that he had established to promote education and social services in Nebraska. Kiewit left approximately 3% of his $186-million estate to his widow, his son, Peter Jr., 60, and other relatives. Peter, a successful Phoenix lawyer, was surprised by the $1.5-million legacy he received at age 53. Says he, "I was raised to expect nothing, and supported myself all my life. In the end, I think my father was saying from the grave that he approved."

Father's passing :

Kiewit Corporation

Founded 1884 (Kiewit Brothers)

Headquarters Kiewit Plaza / Omaha, Nebraska, U.S.

Key people Rick Lanoha (CEO)

Revenue $12,338.0 million USD (2012)

Net income $581.0 million USD (2011)

Number of employees 22,000 [1] (2017)

Website www.kiewit.com

Kiewit Corporation is an employee-owned[2] Fortune 500 contractor[3] based in Omaha, Nebraska. Privately held, it is one of the largest construction and engineering organizations in North America.[4] Recent projects have included several bridge retrofittings in the San Francisco Bay Area, Interstate H-3 project in Hawaii, rebuilding the spillway at Oroville Dam, and building the world's largest geodesic dome at Henry Doorly Zoo in Omaha.[5] Along with significant mining and off-shore operations, the company also contracts small grading (dirt moving) projects for residential or commercial development.

History

The company was founded in 1884 as Kiewit Brothers Masonry Contractors by Peter and Andrew Kiewit, who were of Dutch descent. Their father, John Kiewit, emigrated from The Hague in 1857, where he learned the trade of brickmaking. John Kiewit established a brickyard in Omaha, Nebraska where his sons worked and learned the skills for their masonry business. Early projects included the seven-story Lincoln Hotel in Lincoln as stone masons and the Bekins warehouse as general contractor.[6][7]

The original brothers dissolved their partnership in 1904 and the founding Peter Kiewit would continue as a sole proprietorship. In 1912, two of his sons, Ralph and George Kiewit would join their father as partners in the firm. When the founding Peter Kiewit died in 1914, his son Ralph led the company. George and Ralph Kiewit would later leave the company.

The founder's youngest son, also named Peter Kiewit, joined the firm in 1919. He led the firm from 1924 until his death in 1979. This is the Peter Kiewit known for building one of the largest construction companies in the world. He was also very active in the Omaha area, including leadership of the Knights of Ak-Sar-Ben.[6]

Notable projects in the 1920s by the firm, now known by Peter Kiewit Sons, included the Livestock Exchange Building (1926), the Burlington railroad depot (Lincoln), the Nebraska State Capitol Tower (1927), Joslyn Art Museum (1928), and Union Station (1929). In 1931, Peter Kiewit incorporated the company as Peter Kiewit Sons' Co. The firm would begin building transportation projects during the Great Depression.[6][7]

Walter Scott, was also a key figure in the growth of Kiewit. Scott was initially hired to work on the tower project at the Nebraska State Capitol and spent the remainder of his career at Kiewit becoming chief engineer.[6] His son would not only work for Kiewit, but also rise to the position of CEO.[8]

Leadership

Rick Lanoha is the current chief executive officer of Kiewit Corporation. His predecessors include Peter Kiewit, Bob Wilson, Walter Scott Jr. Ken Stinson and Bruce E. Grewcock. Prior to Grewcock's retirement, on January 1st 2020, Lanoha had served as president and chief operating officer since 2016 and was elected to Kiewit's board of directors in 2009[9]

Walter Scott, Jr. was first elected to the Peter Kiewit Sons' Incorporated board in 1964. In 1979, he was elected president. When Peter Kiewit died later that same year, Scott was selected to succeed him as chairman.

Expansions

In 1963, Peter Kiewit bought the *Omaha World-Herald* to keep it locally owned. Under the terms of his will, the employees bought the paper in 1979.

Starting in 1985 (Kiewit built MFS in the early 1990s; Level 3 was built in the 1997 to 1999 circa), Kiewit also constructed a nationwide fiber optic network. This network was later spun off as Level 3 Communications, which became the formal successor corporation to the original Peter Kiewit Sons'.[10]

KIEWIT BREAKS WITH TRADITION

By Steven Greenhouse

July 13, 1984

Link - [HN00ZI][GDrive]

Although Peter Kiewit Sons' Inc. is not well known around the nation, the construction and mining company is the stuff of legend in this agribusiness center along the Missouri River.

On June 29 the company announced plans to acquire the Continental Group, a diversified packaging company based in Stamford, Conn., in a $2.8 billion deal. It would be the first major diversification for Kiewit, which was founded here one hundred years ago as a brick manufacturing concern.

The founder, Peter Kiewit, was the son of a poor Dutch immigrant. His youngest son, also named Peter, took over the company in 1931 and built it into one of North America's largest construction companies. In doing so, the younger Kiewit, who dropped out of college to join the company, became a millionaire hundreds of times over.

He died five years ago at the age of 79, and until two weeks ago the new management had closely followed the lessons he taught: Work hard and stick to the businesses you know best.

But with the deal to take over Continental, Kiewit management broke sharply with company tradition. And many analysts are wondering whether Kiewit is biting off more than it can chew.

Making Tough Decisions

"I don't know if at the age of 79, Peter would have done it, but he just might have at age 50," said Walter Scott Jr., the soft-spoken, 53-year-old chairman and president of Kiewit, in discussing the deal, which is expected to be completed this fall. Mr. Scott, whose father was the first engineer Mr. Kiewit ever hired, said that before making tough decisions, he often asks himself what "Peter" would have done.

"If you take the contracting business during the time Peter was involved, it was almost an uninterrupted period of expansion, but in the last five or six years that has changed," Mr. Scott said, in explaining the company's acquisition plans. "Our primary businesses - mining and contracting - are now mature businesses. Although we expect to continue to be in them, we concluded that our greatest potential for growth was elsewhere."

And elsewhere turned out to be Continental Group, which has almost twice the revenues of the acquiring company. Kiewit's financial figures are hard to obtain because it is privately held. But Donald L. Sturm, chief financial officer and senior vice president at Kiewit, said it had revenues of about $1.5 billion last year and earned "more than $150 million."

The company has about $1.4 billion in assets and seems to have recovered from a bid-rigging scandal that tarnished its reputation two years ago. Its financial strength was demonstrated by its ability to arrange a $2 billion loan package in just two days to cement the deal.

Mr. Sturm, a 52-year-old lawyer, said the company, which is owned by its employees, had accumulated $500 million in cash and was looking to invest. "We were required to look beyond construction and coal because there was no opportunity to reinvest the funds on a profitable basis," he said.

So when David Murdock, the West Coast financier, approached Kiewit about acquiring Continental, he found a receptive audience. A week later, the deal was clinched, with Kiewit controlling 80 percent of the purchasing group and Mr. Murdock the remainder.

But there is little chance that Kiewit will keep Continental intact.

"They're taking on a big business," said Cornelius W. Thornton, an analyst with the First Boston Corporation. "They're talking about $2.8 billion. It would suggest that even with Continental's healthy cash flow, they would want to shed some of that debt as fast as they can. I think they will want to sell off some parts of Continental."

Mr. Sturm acknowledged that "we are going to have to dispose" of some of Continental, which has assets in packaging, insurance, forest products and oil and gas. Mr. Scott and Mr. Sturm said that they did not yet know which assets would be sold, saying that it would depend on which divisions received the best offers. In addition, they said they planned to leave Continental's management more or less alone because it was, in their view, doing such a good job.

Construction Challenges

Taking over Continental is only the latest in a series of challenges for Kiewit. Those have included taking just 90 days to build 760 barracks buildings, each housing 64 men, at Fort Lewis, Wash., in 1941. The company also marshaled 5,000 workers to build an airbase with a 10,000-foot runway in Greenland in 1951.

Its other projects have included the 63d Street subway tunnel between Manhattan and Queens, the seven- mile-long San Mateo-Hayward bridge over San Francisco Bay, and the mile-long, $425 million Fort McHenry tube in the Baltimore harbor.

A company spokesman said Kiewit has built $2.1 billion in highways and $825 million in tunnels since 1970. It has also built missile bases and parts of the trans-Alaska pipeline, as well as nuclear, hydroelectric and geothermal power plants.

In Omaha, moreover, the younger Mr. Kiewit, who started with the family company as a bricklayer, played the role of developer extraordinaire. He constructed many of the city's most ambitious products, leaving a personal stamp on the Omaha landscape.

He started with the Omaha Livestock Exchange, a brick, Romanesque tower finished in 1924. Later projects included Omaha's art museum, its most prestigious hotel, the Mutual of Omaha Insurance Company complex, and, coincidentally, a factory for the Continental Can Company, which was the Continental Group's original name.

Civic Participation

But the Kiewit reach extends far beyond construction in Omaha. In 1962, when he feared that outsiders were going to buy the city's major newspaper, The Omaha World-Herald, he moved quickly to buy it. His will provided for the sale of the newspaper to its employees. In addition, it provided for the establishment of a charitable foundation with a bequest of more than $100 million.

In the late 1960's, the construction company expanded into coal mining as a way of using its heavy equipment during the winter. It now mines more than 20 million tons a year in Wyoming and Montana. Mr. Sturm said coal accounts for a quarter of the company's revenues but half its profits, thanks to several long-term supply contracts it signed in the 1970's when coal prices were high.

Kiewit agreed in May to join the Occidental Petroleum Corporation in a $600 million venture to build a huge coal mine in China. Mr. Murdock, the partner in the Continental purchase, is Occidental's largest shareholder.

Expanding its energy interests, Kiewit has in the last three years bought 23 percent of Mapco, a coal, oil and gas company based in Tulsa, Okla. In another diversification move, it bought the Empire Savings, Building and Loan Association, Denver's largest savings and loan.

In Omaha, many think that the secret of Kiewit's success is hard work and employee loyalty.

"When you went to work for Kiewit, you dedicated yourself to Kiewit," said Warren E. Buffett, the Omaha investor and chairman of Berkshire Hathaway Inc. "The workers identify with the company the same way Nebraskans identify with the Nebraska football team."

To Mr. Sturm, growth was just a matter of shared self-interest.

"If you want the principal reason for the company's success," Mr. Sturm said, "it's that we're owned by our employees. That makes everyone feel like an owner, which means that every one works harder, is more dedicated and is willing to go that extra inch."

The stock is owned by about 900 of Kiewit's top managers and senior salaried employees. The company has an additional 1,800 salaried, white- collar employees and, depending on the season and the number of contracts, between 7,000 and 15,000 construction workers.

And thanks to the stock ownership program, dozens of Kiewit managers became millionaires when they sold their stock at retirement, as the company requires.

Costs Kept Low

Another key to the company's success has been its ability to underbid competitors for many big and profitable projects. The reason, industry experts say, is that Kiewit's costs are often lower than its rivals because it owns almost all the construction equipment it needs and has so much cash that it does not have to borrow for construction financing.

Even adversity has not derailed the company for long. Two years ago three low-level, regional executives were convicted of rigging bids. The company has taken pains, including the dismissal of employees, to insure that such a scandal is not repeated. "We had a few people who got down to the low morals of their particular marketplace," Mr. Sturm said. "We've taken measures to make sure that doesn't happen again."

June 12, 1985 (June 12) - NYTImes - "20% Interest Sold In Kiewit-Murdock"

Source : [HN00ZH][GDrive]

Peter Kiewit Sons' Inc., the Omaha-based construction and mining company, has purchased David H. Murdock's 20 percent equity interest in Kiewit-Murdock Inc., an investment company formed last year to acquire the Continental Group, the packaging company based in Stamford, Conn.

Investment community sources said the Pacific Holding Corporation, a closely held Los Angeles-based investment company controlled by Mr. Murdock, sold its interest in Kiewit-Murdock for about $200 million.

In a telephone interview from Los Angeles, Mr. Murdock said the deal was amicable. He added that Peter Kiewit Sons', which is also closely held, would continue to do construction work for him and that he hoped to enter future joint investments with the company.

"I didn't turn sour on the can business," Mr. Murdock said, "I just didn't see that I wanted to stay in the can business."

He continued, "In terms of day-to-day management, they said they wanted the whole thing, and I said, 'If you want it, you got it.' "

Kiewit-Murdock Inc. said that Donald L. Sturm, a senior vice president and director of Kiewit, had been elected its chairman, president and chief executive. The company also said Mr. Murdock and Raymond H. Henze, a senior vice president of Pacific Holding, had resigned as directors.

Mr. Murdock learned that Continental Group was up for sale last year and persuaded his longtime business acquaintance, Walter Scott, Kiewit's chairman, to join him in a $2.75 billion bid, which was successful. Investment community sources said that Mr. Murdock had invested $150 million and Kiewit Sons' $600 million to purchase Continental, and banks provided $2 billion in loans.

1972 (Feb 25 - Missile Award to Kiewit

Feb. 25, 1972

[HN00ZG][GDrive]

The Peter Kiewit Sons Company announced yesterday the receipt of a $110.9 - million Army award for work on the safeguard ballistic missile system in Montana.

Kiewit Corporation

Contents [show]

The Kiewit Corporation is a Fortune 500 contractor business headquartered in Omaha. It is an employee-owned privately held company, founded in 1884 as the Kiewit Brothers.

In 1884, the brothers Peter and Andrew Kiewit, two bricklayers of Dutch descent, founded the company that would eventually become the Kiewit Corporation. For a large chunk of the 20th century, the company was headed by the founder's youngest son – also named Peter Kiewit, and it was during his leadership that the business grew to become one of the world's major construction companies.

A lot of landmark infrastructure in the United States has been built by Kiewit, especially in the western states. The Flaming Gorge Dam in Utah, the Garrison Dam in North Dakota, the Montecillo Dam near Sacramento, and the 152-mile Friant-Kern Canal that brings water to California's Central Valley are just a few examples.

Many parts of the United States interstate highway system was also built by Kiewit, such as the Eisenhower Tunnel through the Colorado Rockies and the Fort McHenry Tunnel beneath Baltimore Harbor. Kiewit was also responsible for making the tricky sections of highway that runs through the Virgin River Canyon in Arizona and the Glenwood Canyon in Colorado.

Throughout is life, Peter Kiewit the younger was very devoted to his hometown Omaha and did for instance purchase the the newspaper Omaha World-Herald in 1963 just to keep it locally owned. Before he died, Kiewit left instructions in his will to ensure that the paper would remain locally owned, with a large part of the plan securing employee ownership.

Today, the Kiewit Corporation is one of the largest contractor companies in the world, and they have for instance build the world's biggest geodesic dome for the Henry Doorly Zoo in Omaha. Their fields of expertise include construction, welding, mining, and off-shore operations.

The Kiewit Corporation is subdivided into regional companies and divisions, that are then further divided into geographical districts. A lot of the administration is centralized to the corporate offices in Omaha.

Kiewit Plaza

Kiewit Plaza is where you'll find the headquarters for the Kiewit Corporation. It is a modernist-style high-rise office building, erected in 1960-1961 on 3555 Farnam Street, at the corner of S 36th street.

Background

The two brothers

In 1884, the brothers Peter and Andrew Kiewit formed a masonry partnership in Omaha and called it the Kiewit Brothers. They were the sons of a brick maker of Dutch descent who had moved to Omaha in the 1870s.

1889 is an important milestone in the early history of the Kiewit Brothers, since this is when they were contracted to build the 7-story Lincoln Hotel. At the turn of the century, the brothers ventured into general contracting, taking on responsibilities for the construction of the Bekins Warehouse.

In 1904, the partnership was dissolved, and Peter Kiewit continued the businesses as sole proprietor.

Peter Kiewit and his sons

In 1912, the 23-year-old Ralph and 21-year-old George joined their father Peter Kiewit as partners in the business. Two years later, Peter Kiewit died, and Ralph took over the leadership. Back then, the youngest son – also named Peter – was only 14 years old.

Another milestone was reached in 1924, as the now 40-year-old businesses landed its very first million-dollar contract: building the ten-story Livestock Exchange Building in the meat-packing district of South Omaha. By this point, Peter the younger had also become heavily involved in the firm, working as a project superintendent. 1924 was also the year when George left the firm, leaving it to his two brothers.

Ralph & Peter

After George's departure, Peter took charge of the field operations while Ralph focused on supervising estimations and bidding activities. During the second half of the 1920s, the firm built several notable buildings, including the Nebraska State Capitol Tower in 1927, the Joslyn Art Museum in 1928 and the Union Station in 1929. **For the Nebraska State Capital Tower project, Peter Kiewit recruited a man named Walter Scott, who would eventually turn out to be an very important man in the history of the business.**

In 1931, Ralph left Omaha for California. Peter dissolved the family business and replaced it with the company Peter Kiewit Sons', Co.

Peter Kiewit Sons' starts making highways

When Peter Kiewit the younger formed Peter Kiewit Sons', assets valued at $125,000 were put into the company. To avoid cash-flow problems, and to the make the staff more motivated, Peter decided to let key managers buy shares in the new company if they wanted to. Peter remained majority shareholder and was also president of the company.

Times weren't easy for the new company, as the United States were going through **the Great Depression and the house building sector was in a huge slump. Peter found a niche that could help them survive through the lean years: tax-funded highway construction projects. In order to carry it off, he assembled a core leadership group consisting of four men who all became directors and large shareholders of the company: Walter Scott, Homer Scott (not related to Walter), Ted Armstrong, and George Holling.** Soon, Kiewit Sons' were taking on highway projects not just in Nebraska but out of state as well, in places such as Colorado, Wyoming and North Dakota.

In 1939, the company opened its first district office. It was located in Sheridan, Wyoming, and led by Homer Scott.

Military contracts

Being agile and capable of changing with the times had become somewhat of a hallmark for the company, and in 1939 they complemented their highway business with a $7.5 million contract to build army barracks. The project wasn't just the company's biggest one so far – it also had to be completed in 90 days and the barracks were to be built in Fort Lewis, Washington, far away from Nebraska. As if this wasn't enough, the army changed their plans when work on the barracks had just begun in – they wanted to increase the scope of the contract to more than twice as many buildings, from 760 to 1540, but without moving the deadline. Kiewit Sons' agreed, and this became the start of a series of lucrative army contracts for the Omaha company. It also kicked the company's geographical expansion into high gear, as the army needed facilities built from the Pacific Coast (including Alaska) through the Rocky Mountains states and into the Great Plains region.

When the army needed something built rapidly and to standard, they knew they could count on Kiewit Sons' to get the job done. Throughout WWII, the company created army bases, airfields and more. In their native Omaha, they built the impressive Martin Bomber Plant just south of the city. Before the war was over, Kiewit had done more than $500 million of military work.

Mining

Instead of just being happy with the military construction contracts, Kiewit Sons' broadened their scope and started getting involved in mining. It was an offshoot to their military ventures, since coal from the Big Horn Mine in Wyoming was needed at the Hanford Project in Washington State. This was were the top-secret Manhattan Project was carried out.

Greenland

With their previous experience from military work and dealing with the bitter Alaskan cold, Kiewit Sons' was not a surprising choice when the U.S. Army needed to create a top-secret air base on Greenland in the early 1950s. To carry out the project, Kiewit had to hire and train 5,000 workers, and also handle perilous transports through icy waters.

Kiewit Son's didn't leave Greenland until the second half of the 1960s. Not only did they create an airbase on Greenland, they also made the enormous radar screens required for the Ballistic Missile Early Warning System (BMEWS) and built radar domes on the ice cap for the eastern end of the Distant Early Warning (DEW) line.

Nuclear

The $1.2 billion Gaseous Diffusion Plant Project at Portsmouth, Ohio was one of the biggest construction contracts ever awarded by the United States government. The plant was needed for the refinement of uranium for both military and civilian use. Who got the contract? Kiewit Sons'.

For the differing FUDS for "Peter Kiewit Sons Co" (COD060613403)[1] at a different Colorado location from the namesake Air Force Plant (as in 1965 United States v. Peter Kiewit Sons' Co., 45 F. 2d 879[2]), see List of Superfund sites in Colorado.

Air Force Plant Peter J. Kiewit and Sons **(AFP PJKS,[3] AFP #79)[4] is a Formerly Used Defense Site (CO7570090038) at the Colorado Front Range and used during the Cold War (1957-1968) to provide "rocket assembly, engine testing, and research and development"[2]) for the Titan missile complexes southeast of Denver (construction began April 1959)**. The 464 acres (188 ha) of former "Martin Missile Test Site 1"[5] was "deeded" to the USAF in 1957, was subsequently operated by the builder (Glenn L. Martin Company), was listed on the EPA's National Priorities List on November 21, 1989; and remained USAF property until transferred to Lockheed Martin in February 2001.[2] The site is used by, and entirely within, the secure Lockheed Martin/United Launch Alliance Waterton Canyon facility of 5,200 acres (2,100 ha)[2] that produces Titan IV launch vehicles and the GPS III space vehicles. Entirely within the East Fork Brush Creek watershed,[6] the former USAF firearms ranges used by PJKS military police remains along the creek, is managed by the Skyline Hunting and Fishing Club,[7] and is used for periodic Jefferson County police and local Boy Scout training.

HGM-25A Titan I ICBMs were liquid-fueled rockets using LOX/RP-1 propellant which required the missiles to periodically be removed from the launch silos for servicing. Environmental sites at PJKS include 59 within six operable units (e.g., OU1, OU4, & OU6), and there are six areas of concern (12 of 14 underground tanks have been removed). Groundwater contaminants include trichloroethene (TCE), hydrazine, vinyl chloride, benzene, and nitrate. In fiscal year 1996, "technical work groups were formed with EPA, the State of Colorado, USGS, and the U.S. Army Corps of Engineers to support RI site characterization and risk assessment."[8]

Series: Minuteman Missiles and the Nuclear Arms Race

ARTICLE

A Silo A Day

Minuteman Missile National Historic Site

A South Dakota missile silo under construction

NPS

On September 11, 1961, the groundbreaking ceremony for Ellsworth AFB's Minuteman installations took place at Site L-6 near Bear Butte. The festivities started with a bang. While the Sturgis High School band played, representatives from **Boeing, Kiewit, the Corps of Engineers, and Ellsworth AFB** set off an explosive charge to begin the excavation.

Despite extreme cold, high winds, and heavy snowfall, construction proceeded at a furious pace through the winter of 1961-62. In mid-December, the Corps of Engineers told reporters that "men are working seven days a week, three shifts a day on Minuteman construction." A Corps spokesman said that crews were "able to dig five silo emplacements simultaneously. Each takes from four to ten days . . . " The first squadron, near Wall, was well underway, said the Corps, and work ,on the second squadron, near Union Center, had already started.

In February 1962, General Delmar Wilson told the Rapid City Chamber of Commerce that despite an ongoing labor dispute between **Peter Kiewit Sons** and the Ironworkers Union, South Dakota's ICBM deployment suffered fewer work stoppages than any missile program in the Nation. "We're all out . . . to assure that our way of life is maintained," stated Wilson. "This missile project ... is the number one project in the country today. If this guy in Russia wants to start a show, we'll be there to put a hole in him to the best of our ability. "

By early summer of 1963, the steel fabrication was finished at all 165 South Dakota sites, and crews were completing the silos at the rate of one per day. On the last day of June, the first 20 silos were turned over to the Strategic Air Command. On October 23, the Nation's second wing of Minuteman ICBMs was fully operational. The work was completed nearly three weeks ahead of schedule.

Minuteman MissileHistoric Resource Study

Section II — Life on the South Dakota Plains: Before, During, and After Minuteman

Chapter 3:

Minuteman Missile Sites in South Dakota (1960s-80s)

In the late 1950s the Air Force chose South Dakota as one of the locations to base the nation's nuclear arsenal with the installation of Minuteman missiles. The Army Corps of Engineers (Army Corps) began surveying sites throughout western South Dakota by the fall of 1960, and subsequently began negotiating with landowners for rights-of-entry to construct Launch Facilities (LF) and Launch Control Facilities (LCF) on their property. The Minuteman I Intercontinental Ballistic Missile (ICBM) construction program at Ellsworth Air Force Base progressed rapidly. Under supervision of the Army Corps , Peter Kiewit and Sons' Inc. (Kiewit Company), the Boeing Corporation, and their subcontractors began construction of the 150 LFs and fifteen LCFs during the fall of 1961. Their work, both in construction and then in activation of the Minuteman I, furthered the nation's defense program, but also affected western South Dakota economically and socially, an influence that remained through the Minuteman's deactivation.

Site Location

The Air Force's policy on site selection in South Dakota was multifaceted. Sites were primarily selected by balancing a variety of criteria, including maximizing Minuteman operations, minimizing each sites' vulnerability to sabotage, using the taxpayers' money wisely, and adapting individual sites to construction and operational needs, all with an eye to unique qualities of individual locations. [204] Other factors that contributed to the selection of sites were the physical features of the land, including the geology and terrain of the area, the types of soil, and the amount of available ground water. [205]

For cost and efficiency, the Air Force located missile sites near the existing Ellsworth Air Force Base in order to provide logistical support to the facilities. The missiles were located within an area approximately one hundred miles east and north of the base, in an expanse covering approximately 13,500 square miles of western South Dakota. The three Minuteman I ICBM squadrons at Ellsworth Air Force Base, each consisting of five LCFs and fifty LFs, were located in the vicinity of the communities of Wall, Union Center, and Belle Fourche. [206]

The Air Force positioned each missile flight (one LCF and ten LFs) in the same geographic area, but individual LFs could not be directly adjacent to another LF or the LCF. Minimally, the Air Force required LFs and LCFs to be geographically separated by an area large enough to withstand a ten-megaton explosion at an adjacent facility. Air Force specifications also required that the sites be separated so multiple facilities could not be targeted together. [207] The Air Force additionally attempted to select sites that would have the least adverse effect on nearby communities and private property. [208]

Land Purchase

The Air Force selected LF and LCF sites based on the surveys completed by the Army Corps, Omaha District Office. Prior to construction of the missile sites in South Dakota, right-of-entry, easements, and land purchase agreements needed to be made with hundreds of property owners. The acquisition for the 150 LFs, fifteen LCFs, and approximately 1,732 miles of Hardened Intersite Cable System (HICS) connecting the facilities included three phases. The first phase was securing right-of-entry for survey and exploration of proposed sites. Next, the Air Force worked with landowners to obtain right-of-entry for facility construction. The final phase included negotiations for land purchase or permanent easements and compensation for damages during the construction of the facilities. [209]

Phase one began in the fall of 1960. The right-of-entry Air Force representatives inspected potential sites throughout western South Dakota to assess the soil, geology, terrain, and ground water for suitability for site construction. [210] By early 1961 the locations for the LFs and LCFs were identified and HICS routes mapped. Following site selection, the Army Corps solicited landowner's signatures for right-of-entry to commence construction of the LFs and LCFs on their property. For the construction of each LCF or LF the Air Force required temporary construction easements of between four to six acres for construction equipment and dirt removed from the silos. [211] Following the right-of-entry for construction, the Army Corps negotiated with landowners to purchase the land. In land purchase and easement negotiations, the government was required to provide just compensation, defined as fair market value. [212]

In addition to land purchase, the government obtained permanent easements at the LF and LCF sites. It needed these easements in order to restrict land use in the area surrounding each LF and LCF to certain types of construction and agricultural activities. [213] The government also obtained permanent easements for the access road at both the LF and LCF and for the azimuth markers at each LF site, which were located outside of the fence and used to site the missile. Following construction the land was inspected by a real estate representative of the Army Corps and through negotiation an agreement was made with the owner for a cash settlement of any damages. [214]

Army Corps representatives negotiated with several hundred more property owners for easements for the underground HICS connecting the LFs and LCFs. These cables, installed four to eight feet below ground and used to transmit data between missile sites, required a temporary construction easement of thirty-five feet in width for approximately 1,732 miles between all 165 sites. After construction was complete, the government obtained a permanent easement for a path sixteen and one-half feet wide. [215] Following installation of the HICS, landowners could return to using the land above the cable for normal ranching or agricultural activities.

Such large-scale construction was not without its inconveniences, and to address some of the issues pertaining to land acquisition during this initial period, the Army Corps real estate field office distributed a pamphlet to property owners in western South Dakota titled "Facts About Minuteman Land Acquisition." The pamphlet promised landowners that the government would negotiate for the purchase of property and address any damages and losses. The pamphlet reminded the property owners that the Constitution permits the taking of private property for public use as long as the landowner was paid "just compensation." [216] Even with the issue of national security at stake, policymakers had no desire simply to confiscate land. If the landowners and the government could not agree on compensation, however, the government had the right to acquire the land through condemnation. A declaration of taking was filed and compensation was deposited with the court for the property owner. Negotiations continued and if an agreement could not be made the condemnation case would be brought to trial.

Minuteman Missile Area Landowners Association

While construction crews built some of the Minuteman sites in South Dakota on land already owned by the government, such as LF Delta-09, contractors constructed most of the sites on private property. During the site-selection process, some landowners did not feel that the Army Corps provided enough information to sign rights-of-entry to their property. To ensure that the government took landowners' rights into consideration during site selection and fairly compensated landowners, a group of farmers and ranchers formed the Minuteman Missile Area Landowners Association (MALA) in the early 1960s.MALA disseminated information to area landowners, believing that working collectively would aid the defense effort while safeguarding their private interests.

Members paid a minimal fee of one dollar to participate in the organization, primarily to cover the cost of postage and mailings. The MALA's first president was Eugene Pellegrin of Enning, South Dakota, and the first vice president was Cecil Hayes of Elm Springs, South Dakota. Eight additional members, including Burle Dartt, Ray Naescher, Ben Paulsen, Tony Oergerli, Robert Simpfendoerfer, Delbert Paulsen, Ferdinand Schroeder, and Leonel Jensen, served as directors to assist in collecting and distributing information. [217] In addition to nearly 150 MALA members supporting their cause, United States Senator Francis H. Case also attempted to assist negotiations between the landowners and the Air Force and Army Corps. Although Case was a longtime proponent of strong national defense and a supporter of the Minuteman I missile program at Ellsworth Air Force Base, he often corresponded with the landowner organization and the Army Corps concerning the project and advocated for fair and timely compensation. [218]

Most landowners understood that the national defense program required the installation of Minuteman missiles, and the technical reasons why the Air Force required use of their land. Prior to signing any agreements, however, MALA members wanted the government to address the disadvantages of having a LF or LCF constructed within their property. Many landowners were concerned that the location of the proposed sites would disrupt irrigation systems,

take irreplaceable land, or interfere with agricultural operations. While their primary stated goal was to obtain a reasonable settlement for land and construction damages, the group also wanted to minimize the effects of the missile system upon nearby schools, roads, and the local police force. [219]

Prior to signing rights-of-entry needed for construction, the MALA voiced their concerns with Air Force and Army Corps personnel at several meetings in Rapid City in 1960 and 1961. MALA members questioned how the Air Force selected locations for the LFs and LCFs. Individual MALA members desired to know if selected sites could be moved to sections of their property less desirable for agricultural purposes. [220] In early April 1961, an Army Corps real estate representative explained that the missiles were part of an interrelated system and the location could not be altered aside from minor changes. [221] One property owner offered to donate the land if the Air Force would move the proposed LF to a corner of the wheat field instead of in the middle. His offer was rejected, and, in this case, the Air Force did not alter the proposed site for this facility. [222]

MALA members also pressed the Air Force at these meetings for further information about compensation for their land and losses. Many wanted to know what assessment they should expect for their property, and if they would receive compensation for damages incurred during construction or from decreases in land value due to the presence of the missiles in the area. [223] Army Corps officials responded that landowners were entitled to fair compensation for their losses and that the dollar value would be reached through negotiation between the government agency and individual property owners. Compensation for damages would be negotiated in much the same way. [224] Although many landowners received compensation for their land and losses, some felt the settlement offered was inadequate. [225]

After months of meetings and negotiations, seventy-five percent of the property owners of proposed missile sites signed rights-of-entry agreements by July of 1961. At the same time, approximately ninety percent of landowners involved with the underground cables had also signed agreements. [226] MALA president Pellegrin stated in a newspaper article that many of the property owners who refused to sign the agreement were negotiating for damages unique to their property. [227] In some cases, property owners never signed the rights-of-entry agreement needed to begin construction and in these cases, the Army Corps filed declarations of taking and deposited money with the court for the property owner. The Army Corps based the compensation on the government's original estimate of fair market value for the property. [228]

Despite efforts of the MALA to protect their rights and obtain compensation for their losses, some members of the public and government criticized the organization's members. They condemned landowners for slowing the defense effort, termed them unpatriotic, and accused them of holding up new business created by the influx of construction workers and additional Air Force officers. [229] The Air Force and Army Corps often reminded members of the MALA and other residents of western South Dakota of the importance of the Minuteman I ICBM program to the security of the United States. For example, the land acquisition pamphlet distributed to property owners stated, "like its prototype, the Minuteman of 1774, this immensely-important project for our national defense is authorized by the Congress of the United States." [230] Criticism aside, however, not every delay in Minuteman construction could be pinned on reluctant landowners. As late as March 1961, Congress had not yet fully appropriated the funding for the Minuteman I ICBM missile program at Ellsworth Air Force Base. Therefore, property owners did not stall construction of the sites in South Dakota or the nation's defense effort. [231] In reality, the land acquisition and construction of the Minuteman I missile facilities in South Dakota was an accelerated program that exceeded many expectations. Approximately one year after Army Corps representatives started testing soil and mapping missile facilities contractors began construction. After the construction of the LFs and LCFs in western South Dakota the MALA disbanded. The organization remained inactive until the early 1990s when the Air Force began the deactivation process of the Minuteman II ICBMs and a new generation of property owners worked together to disseminate information and provide support.

Chapter 3:

Minuteman Missile Sites in South Dakota (1960s-80s) (continued)

Site Construction

In 1960 the U.S. Army established the Corps of Engineers Ballistic Missile Construction Office (CEBMCO) as an independent organization to supervise missile site construction across the country, including Ellsworth Air Force Base. With the new agency, the construction of ICBM facilities fell under uniform and centralized control. [232] The commanding officer of CEBMCO appointed weapon system directors to manage the construction of Minuteman facilities at Ellsworth Air Force Base, as well as other ICBM construction sites. These directors worked at area offices, such as the one at Ellsworth Air Force Base, to directly supervise the construction of numerous contractors for the multiple phases of the construction process. [233]

CEBMCO originated with a staff of twenty-seven to supervise the construction of the missile facilities throughout the United States. That number grew to three thousand employees working in seventeen states by the mid-1960s. **In South Dakota, CEBMCO appointed Colonel Sidney T. Martin to direct the construction project, while Lieutenant Colonel George V. Svoboda was named deputy engineer, Lieutenant Colonel James M. Gale assistant engineer, and Warren Withee served as the Chief of the Construction Branch. [234] At the time, constructing missile facilities was one of the largest construction projects undertaken by the Army Corps. In** the 1960s CEBMCO and its predecessor agencies supervised the construction of 1,200 missile facility sites nationwide, including the 165 sites in South Dakota. [235]

Although CEBMCO staff at Ellsworth did not physically design or construct the LFs or LCFs, they were responsible for soliciting bids, selecting contractors, and reviewing plans. After supervising contractors during construction, CEBMCO aided the Air Force site activation task force in fitting the silos with operational missiles. [236]

In the summer of 1961 the Home Office Special Projects District at Kiewit Company in Omaha, Nebraska, won the bid to construct the Minuteman I ICBM silos for Ellsworth Air Force Base in South Dakota. The Kiewit Company bid estimate of $56,220,274 was nearly $10 million less than government projections. [237]

Using the designs developed by Parsons-Staven, a Los Angeles architectural-engineering firm, Kiewit Company was the primary contractor for the Minuteman I ICBM facilities in South Dakota. [238] The contract included preparing sites for facility construction and installing facilities using prefabricated parts. They were also responsible for negotiating with landowners over damages caused by the storage of excess dirt excavated from the silo shaft.

Groundbreaking ceremonies for the construction of the Minuteman I ICBM silos in South Dakota took place on 11 September 1961 in front of a crowd of approximately two hundred on-lookers at a site later known as Lima-06, located just north of Sturgis. Instead of the traditional shoveling of dirt to symbolize the start of construction, a small explosion signified the power of this immense undertaking. The ceremony theme was "Partners for Peace." [239]

To make for a more efficient construction process, contractors assigned crews specific tasks, which they then performed at numerous sites. Crews assigned to the Minuteman construction project in South Dakota varied in size from four to thirty, depending on the complexity of their task. [240] The first step in constructing the LFs was the excavation and grading at each site. The construction crew assigned this task used a bulldozer and clam shovel to create a circular cut that they then excavated to a depth of approximately thirty-five feet. After this task, the crew moved on to another site to complete the same task until all 150 LFs were excavated. A second crew moved in and proceeded to dig the shaft for the silo using a large auger. The shaft was a circular hole with a diameter approximately fifteen to eighteen feet and extended over eighty feet below the ground. The next task involved a third crew that poured a concrete deflector plate into the bottom of the shaft. After this crew secured the bottom of the hole, steel contractors lowered a twenty-five-ton, sixty-two-foot prefabricated steel liner into position. The liner, which formed the skeleton of the silo, included a quarter-inch steel plate and rings of reinforced bars. Contractors then poured concrete around the exterior of the steel liner, forming a twelve-inch-thick wall. Additional crews constructed a lower equipment room around the silo and a support building adjacent to the silo, both of reinforced concrete and below ground level. Once this stage was complete, crews backfilled the sites with dirt originally excavated for the silo and facility. [241]

Kiewit Company subcontracted much of the work to other firms. For example, Summit Construction Company was responsible for the initial site grading, excavating to the approximate thirty-five-foot level, and storing dirt from those tasks. The Gustav Hirsch Organization installed electrical conduit and backfilled the area around the conduit. Natkin and Company installed mechanical pipes and was responsible for the backfill and compaction around them. For the installation of the HICS, Kiewit Company retained American Bridge Design—United States Steel Corporation. [242]

The construction procedure involved moving nearly twenty million cubic yards of dirt for the 150 LFs and fifteen LCFs. In addition, contractors poured nearly one hundred fifty thousand cubic yards of concrete and used thirty-five thousand tons of steel to reinforce the underground facilities. [243] Although the numbers appear large, constructing Minuteman I ICBM LFs was much less challenging than the construction of earlier Atlas and Titan LFs. Minuteman I LFs were smaller than earlier ICBM facilities and they used prefabricated parts and standardized construction techniques. Furthermore, the Minuteman I LFs did not require the elevator that positioned the missile for launch or the complex loading system that burdened earlier missiles. [244]

Despite steps taken to minimize costs and speed deployment, Minuteman construction did not always proceed smoothly. In some instances, work stoppages, weather, and injuries delayed construction of the 165 Minuteman LFs and LCFs in South Dakota. The famously unpredictable plains weather affected the construction of the sites with dust storms, heavy rains, snow, and even severe cold temperatures. Moreover, work at the missile sites in South Dakota stopped on several occasions due to labor difficulties. For example, on 6 June 1962 the American Bridge Company millwright workers went on strike for two days to protest the Kiewit Company's assignment of the setting anchor bolt task to ironworkers, which they believed to be their task. One week later Gustav Hirsch electricians protested the Kiewit Company's requirement that they report for work directly to LFs instead of a central point. [245] Contractors and workers dealt with such problems using "policies, procedures, and methods of adjustment" developed by the Missile Sites Labor Commission, the eleven-person agency appointed by President Kennedy in 1961 to aid in resolving labor disputes at missile and space sites quickly, and therefore without delay to the national defense program. [246]

Worker safety was an important issue at the missile construction sites and the Kiewit Company required employees to wear hard hats. During the two-year intensive construction period employing thousands of workers, sixty-two injuries and two fatalities were reported at the missile facilities in South Dakota. [247] In comparison, Minot Air Force Base in North Dakota experienced thirty-six construction-related injuries and two deaths, while Malmstrom Air Force Base suffered twelve injuries and one fatality. [248] Clearly this was dangerous work, as with all heavy construction, though the Kiewit Company received the National Safety Council's Award of Honor in 1962 for its missile construction efforts. During the second half of that year, the company logged over eight hundred thousand accident-free work hours, offering a safety record due in part to regulations set forth by the Army Corps. For example, the Army Corps required that any excavations at the sites had to have a slope on its bank so it would not cave in on anyone working inside the hole or shaft. [249]

Despite delays and unfortunate incidents, construction in South Dakota was completed by the fall of 1963, in less than two years. Construction of Delta-01 had been completed the previous year on 29 November 1962 at an estimated cost of just over $800,000 and construction of Delta-09 was completed on 26 November 1962 at an estimated cost of $354,500. The final costs for the construction of the Minuteman missiles in South Dakota may have been as high as $75.7 million. 250]

Missile installation

While Kiewit Company and other contractors worked to construct missile facilities throughout western South Dakota, the Boeing Company assembled the actual missiles, and developed much of the ground-support equipment, such as the launch control system, and the security system. More importantly, Boeing ensured that the missiles worked through testing, installed the missiles beginning in February 1963, and maintained them before transfer to the Air Force in the summer and fall of 1963. [251] Delta-01 and Delta-09 were turned over to SAC on 30 June 1963, making them among the first Minuteman sites to be activated at Ellsworth.

The emplacement of the missile in the silo employed skilled crews using a Transporter Erector (TE). After operators backed the TE into place, the missile container was raised to a vertical position over the silo opening. The missile was then freed from its restraining harnesses and a large hoist lowered it into the launcher. Once the missile was in the silo, technicians attached the reentry vehicle on top of the guidance and control system. After installing the reentry vehicle, the missile was aligned and oriented to the North Star and a targeting team set the arming and fusing system. [252] After Boeing finished installing all 150 missiles, the Air Force Systems turned the LFs and LCFs into operational facilities and SAC declared all three Strategic Missile Squadrons (SMS) combat ready on 1 November 1963.

Site Activation

The 44th Strategic Missile Wing (SMW) at Ellsworth Air Force Base was activated on 1 January 1962. Air Force personnel assigned to the 44th Missile Wing began training even while construction and development of missiles for the South Dakota Minuteman program was underway. Ellsworth Air Force Base received its first Minuteman I in February 1963. [253] The Air Force placed the first total flight of Minuteman I ICBMs at Ellsworth Air Force Base on alert status in July 1963 when Base commander, Colonel Kenneth W. Northamer, handed over the keys for the flight to Colonel Virgil M. Cloyd, commander of the 44th SMW. [254] By November 1963, the 66th, 67th, and 68th SMS of the 44th SMW were ready for combat. [255] Each squadron was responsible for five flights of ten missiles, totaling 150 Minuteman I missiles.

Economic and Social Impacts on the Region

Economic Boost to the Region

Like earlier ICBM programs, the Minuteman program had many lasting effects on western South Dakota. The immediate and lasting impacts of the

Minuteman missile program on South Dakota and its people are clearly a part of the missile story and were described by former missileer, Craig Manson,

> "It is a world historical event as well, ... the communities, the people who lived in those communities—they are all part of the story, too. Wall Drug, where many, many, many missile crews had breakfast and lunch, that's kind of part of the story. The Diamond Caf` in Newell, South Dakota, I don't know if it is even still there, but that is part of the story because it would not have been there long if it hadn't been for the missile crews, you know; Bear Butte in western South Dakota, Spearfish and Belle Fourche and towns like Philip and White Owl in the north central part of the state, and all of these communities are part of the story, too, and the way the people in these communities felt, whether they liked it or whether they didn't like it, however they felt about living in the shadow of those missiles." [256]

The large influx of construction workers in the early 1960s and the presence of additional Air Force personnel over the following thirty years affected local communities both economically and socially. Construction of the Ellsworth Air Force Base Titan facilities outside of Sturgis, New Underwood, and Hermosa beginning in late 1959 boosted the local economy and real estate market by providing jobs and demands for housing and goods and services. [257] This trend continued with the construction of the Minuteman I facilities in western South Dakota. Rapid City and smaller communities near the bases and missile sites benefited economically. Examples of increased economic activity brought by the expansion of the staff at Ellsworth Air Force Base are described in the following paragraphs.

The Kiewit Company alone employed nearly three thousand workers at the missile construction sites. [258] The Army Corps and Boeing Company also employed large numbers of staff in South Dakota during the early 1960s. While some of the employees were transient and moved to South Dakota to work on the project, many area residents found work on the construction, therefore stimulating the local economy. [259]

The employment opportunities offered to local residents during the construction of the sites was a significant impact on the local economy. When local resident Gene S. Williams was asked about how the public felt about the missiles being placed in South Dakota, he stated: "Well when they first were being constructed, you know, I think there were a lot of people that looked at them as jobs. It was very good to the local economy. There were high paying jobs, there were a lot of people that had an opportunity to work on the missile sites that, you know, that was probably as good a paying job as you could have gotten anywhere at the time. There were people that picked up skills associated with working on them that have used them the rest of their life." [260] In another case, Thomas Wilson, a Kiewit Company worker who had relocated to South Dakota, was asked about his feelings constructing missile sites, he simply stated, "I figured I had a job." [261]

By some estimates, the influx of new South Dakota residents, most of them union members, helped decide one of the state's closest elections, George McGovern's 1962 Senate victory. As activist Jay Davis recalled: "they were outsiders, they weren't from here, they didn't stay here long but they voted in that election....so George McGovern the great spokesman for peace may have owed his very election, as close as it was, to the workers who were building the missile silos to further the nuclear arms race." [262]

The missile sites themselves brought increased staff to Ellsworth Air Force Base to operate and support the facilities, while the crews and their families became a permanent part of the area's economy and social fabric until the program's deactivation a generation later. "It brought more people into the area," Wall Drug owner Ted Hustead recalled. "There have been a lot of men that were stationed at Ellsworth Air Force Base during the '60s and even today, that found their bride in western South Dakota." [263]

Employment in the area increased not only from direct employment for missile construction, but through the industries that supported the influx of workers. Housing surrounding Ellsworth Air Force Base was needed to accommodate the temporary workers, for example, and Boeing planned three trailer parks in 1961 to accommodate 120 units each. [264] Housing construction and an increase in demand for basic day-to-day needs, such as food and clothing, was an economic boom for the area.

Many local businesses, such as Wall Drug, benefited from the increased population during the Minuteman construction phase. Although the business did not permanently expand due to the presence of construction crews, the workers did have an impact on the business in the early 1960s. During this time Wall Drug would open its doors at 4:30 in the morning to prepare breakfast for the construction crews and pack box lunches. [265] Wall Drug also experienced business from missileers and other Air Force personnel during the years Minuteman I and II ICBMs were on alert status in South Dakota. Many times, LCF personnel would stop at Wall Drug to pick up food for barbeques or personal essentials needed for their three-day alert tour that they may have forgotten on base. [266] With the introduction of new Air Force personnel regularly traveling through the area, Wall Drug began advertising free coffee and donuts for Minuteman missile crews. This eventually led to free coffee and donuts to all veterans, truck drivers, hunters, snowmobilers, and honeymooners. [267]

The local economy continued to benefit from the presence of the Minuteman at Ellsworth Air Force Base into the later part of the twentieth century. During the Force Modernization Program begun in 1971, the Air Force upgraded the Minuteman I missiles of the 44th SMW with Minuteman II missiles. The project continued until March 1973 and employed over three hundred local residents. Local businesses benefited from the sale of supplies for the project. [268] Rapid City, as a regional center in the state, can be attributed in part to the number of people that were stationed at Ellsworth Air Force Base over the years to work at the base and the missile sites.

Public Improvements

In addition to the economic boost, public utilities were also improved during the Minuteman I construction phase. In the spring of 1961 the Air Force initiated an accelerated program to improve 327 miles of roads. Contractors needed improved roads throughout rural, western South Dakota to move heavy equipment to the missile sites, and the U.S. Bureau of Public Roads, Defense Fund provided funds that Congress allocated for road improvements. [269] Many of the improved roads to the missile sites were paved, which was a significant improvement over the area's typically unpaved rural roads. During the missile site construction in South Dakota the federal government designated specific routes for construction crews to follow to the sites. The government contracted with the involved county to conduct road repairs for damage from trucks hauling equipment or materials. In some cases, however, contractors did not follow designated routes, and their crews and equipment inadvertently damaged additional roads. Pennington County billed the government some $150,000 in 1962, to cite one example, to offset the cost of road damage on undesignated routes caused by missile construction. [270] Over the years of Minuteman I and II activation in South Dakota, the road networks continued to be maintained through federal, state and local funds to accommodate Air Force personnel and maintenance activities of the sites.

Many schools also felt a direct impact from the Minuteman construction phase in the early 1960s. The Rapid City schools grew by about one thousand additional students from the nearby Titan project. *The Rapid City Journal* in January 1961 reported that it was anticipated that a similar number of students would also enroll in the Rapid City schools as a result of the Minuteman site construction. [271] It is unknown how much enrollment increased as a result of the influx of Minuteman workers' children during the two years of construction.

Race Relations

The influx of workers during the construction of the missile sites and Ellsworth Air Force Base personnel over the years included people of various ethnic backgrounds, including African Americans. Racial inequality and discrimination, both on and off base, were not isolated to Ellsworth Air Force Base and the Rapid City area, but rather are likely a window into the racial tension and discrimination being experienced by the rest of the country. Rapid City and the region around the base were not very racially diverse, and as a result, African American base personnel pointed out the lack of social centers and ethnic opportunities off base.

Alan Gropman's book, *The Air Force Integrates, 1945-1964*, reports that African American airmen at Ellsworth Air Force Base "were rejected by the local communities, and base officials seemed to be indifferent to their plight. Many business establishments were closed to blacks, all taverns were segregated, and housing for blacks was extremely limited, substandard, and exceptionally expensive." [272] Initially, some members of the Air Force opposed becoming involved in integration issues within the communities outside of the bases, feeling this was outside of their realm of control. The passing of the 1964 Civil Rights Act opened public accommodations to African Americans and allowed the Air Force to take more initiative in integration measures within the communities outside its bases. [273] Following the passage of the Civil Rights Act, some racial tensions continued to some extent both on and off base for air men of different cultural backgrounds.

Oral interviews with past personnel of Ellsworth Air Force Base during the late 1960s through the early 1990s offered varying opinions on the degree of racial tension between African American and minority Air Force personnel and the surrounding community. Ken Bush, an African American stationed at Ellsworth Air Force Base during the mid-1970s and 1980s, stated that "I can honestly say that I was never mistreated anywhere I went." However, he did recall an isolated incident from the 1980s where he and another African American were refused service at an establishment in Rapid City. The matter was taken to the Rapid City Council and the two did not pursue further action. [274] Lieutenant Colonel Robert Wilson stationed at Ellsworth stated that race relations were not a problem on base, but that there were significant problems outside the base community and was surprised how African Americans and Native Americans were treated. [275]

In the Rapid City area there has historically been racial tension between the descendants of Euro-American and Native Americans, but based on the oral interviews collected to date, there is no evidence of significant tensions between the military community at Ellsworth Air Force Base and the surrounding Native American residents, at least in terms of affecting base operations.

Living Next to the Missiles

As is often the case, the presence of a large military base has a significant impact on the region. Ellsworth has become an important fixture in the community. In these ways the Minuteman program left a lasting social and economic imprint on western South Dakota, and not only in ways typically measured by statistics and numbers. An amateur baseball team in Sturgis has adopted the name Titans, referencing the Titan missiles that were once deployed a few miles east of Sturgis. In another example, several streets in Rapid City now bear names reflecting the history and heritage of the base, including Minuteman Drive and Atlas Street.

Initially the missiles brought jobs and money to the area, but as time went on the residents had to learn to deal with nuclear weapons in their backyards. Local rancher Gene S. Williams recalled that a lot of the people that had missiles sites put on their land were from an era that had traveled by horse and buggy or could recall this time, "and now you're putting a hole in the ground for a missile that could launch and go, you know, fifteen thousand miles and blow up millions of people. I mean, these types of things I think were hard for people to even put their arms around." [276]

For the children growing up amongst the missiles and Ellsworth Air Force Base in South Dakota, the Cold War was a part of every day life and evokes vivid memories. Tim Pavek, an environmental engineer at Ellsworth Air Force Base, recalls from his childhood hearing the B-52s. "...I remember when I was a, a little boy in bed here on a hot summer night with the windows open and I'd hear the distant rumble of the B-52s here at Ellsworth taking off. And, and, almost lay in bed shaking wondering if that was a practice mission and they'd come back or if this was the real thing and within a few minutes we'd see the fireballs of, you know, nuclear weapons over western South Dakota. So, having lived next to this Air Force base, you know, we knew that we were a big red-and-white bull's eye on the Soviet map, or that was my perception at the time." [277]

Tim Pavek recalled another childhood memory of the Cold War told to him by a gentleman who grew up in South Dakota, "... he says 'I remember sitting down at the kitchen table with my parents and having a very frank discussion over what we should do with regard to this, the threat of nuclear war. Um, whether we should build a bomb shelter—the people down the street were building a bomb shelter. How we should prepare ourselves for this eventuality.' " [278]

The missiles also perhaps left emotional scars. "And here you're sitting with a thermonuclear device, that is a half mile from your house," local rancher Gene S. Williams commented, "and you know well somebody punches the wrong signal code in or turns the wrong key and you're just vapor. You don't want to dwell on that too much but you also recognize that it wasn't just the enemy that was going to blow you up, you could blow yourselves up." [279] Paradoxically, the missiles themselves, and their LFs and LCFs, were less physically imposing on the state's landscape.

The Cold War Continues

The domestic and local impact of the Minuteman program in economic, political, and even psychological terms, all occurred in the context of sweeping movements within the international system. Whereas the program had begun in an era when only the two superpowers possessed nuclear weapons, by the close of the 1960s at least three nations (Britain, France, and the People's Republic of China) publicly possessed this ultimate power. Other countries, Israel and South Africa (clandestinely), and Pakistan and India (publicly) would join the nuclear club within a generation, while at the time of this writing, North Korea appears on the brink of doing the same. What once was the domain of only superpowers clearly has grown in scope. Minuteman was designed largely for a total global nuclear war, as a deterrent of awful destruction useful for warding off the complete devastation of a large-scale nuclear exchange. Whether such a system would and could help control this new era's increased risk of limited nuclear exchanges remains to be seen.

The superpowers responded to growth of the nuclear club with alarm, and with a surprising amount of cooperation. Each led collective military organizations by the mid-1950s, the North Atlantic Treaty Organization (NATO) and the Warsaw Pact in Europe most famously. Each also believed their own nuclear sword sufficient for defending theirs and their allies' interests. American policymakers thus hesitantly approved of Britain's development of an independent nuclear capability in the 1950s, believing their objection would do little to halt Britain's nuclear program in any event, and loudly criticized France's nuclear program (and subsequent withdrawal from NATO) the following decade. For each of these new nuclear nations, possession of the ultimate weapon symbolized power in a changing world: the power not only to hold its own against lesser foes, but also the power to stand up to Washington or Moscow. "We must rely on the power of the nuclear deterrent," British Prime Minister Harold Macmillan declared, "or we must throw up the sponge!" Moscow proved more adept at halting nuclear development among its allies (who largely lacked the technological and financial resources to develop such expensive weaponry in any event), save for China, which joined the nuclear club only after its break with the Kremlin in the early 1960s. During their 1961 Summit in

Vienna, Kennedy and Soviet leader Nikita Khrushchev even obliquely discussed launching a joint air strike against China's embryonic nuclear program, as both leaders considered an Asian nuclear bomb a threat to their individual and collective interests. Realizing such a move would lead to war, they pursued other paths. [280]

By the 1970s, therefore, the bipolarity of the international system seen in the first Cold War years had given way to a world of multiple points of power. Moscow and Washington remained the two largest powers—and possessed the two largest nuclear arsenals by far—but they were no longer wholly dominant. They retained the power to impose their will on others (as in 1954 in Guatemala or in Hungary in 1956 for the United States, to name only two cases), though as the Soviets would learn in 1968 in Czechoslovakia, and the Americans in Vietnam throughout the 1960s, the use of force often carried negative consequence that far outweighed the potential gains of proving hegemony. In recognition of these changes, and of their profound implications for Asian security in particular, President Richard Nixon slowly developed the practice of what his Secretary of State Henry Kissinger termed "triangular" diplomacy. By warming American relations with China, including development of formal diplomatic and trade ties, Nixon hoped to gain leverage in Europe over the Soviets, forcing them to the negotiating table and towards the lessening of East-West tensions known as dètente. The ongoing quagmire of the Vietnam War and domestic crises such as Watergate ultimately limited Nixon's diplomatic options, but the point of his effort remained: that the second half of the Cold War was far different than the first. There were more nuclear powers, and they possessed even greater stocks of nuclear weapons than before. [281]

Some argued the world was a safer place because of these developments. Others saw the breakdown of Soviet-American relations by the close of the Presidency of James Carter as foreboding and a new and more dangerous phase of the Cold War. The Soviet invasion of Afghanistan in 1979, prompted in part by fear of the new Islamist government in neighboring Iran that drew its power at least in part by anti-Americanism, sparked a new crisis in superpower relations. Washington condemned Moscow's move, which if successful would have given the Kremlin new influence in a region pivotal to the world's oil trade, and American leaders spent heavily to arm Afghan resistance forces in their battle against the Red Army. Ironically, these same forces spawned anti-American Islamist movements such as the Taliban and Al Queda, groups that each began as Mujahadiin fighters, armed by the United States for their battle against Communism. [282]

Carter's final year in office saw renewal of Cold War tensions. Contemporary critics such as Ronald Reagan, who won the White House in 1980, and later conservative historians and pundits eager to give Reagan credit for "winning" the Cold War, harshly rebuked what they perceived to be Carter's tepid opposition of and even tacit acceptance of Communism. Such biased interpretations are largely incorrect. Carter accelerated America's military build-up, and withdrew the Strategic Arms Limitation Talks II (SALT II) from the Senate (where it lacked the votes to pass in any event). He embargoed American wheat and technology exports to the Soviet Union, and even withdrew American participation from the 1980 Olympic Games in Moscow. Like President Truman thirty years before, Carter announced his own "Doctrine," vowing American intervention—most likely nuclear—against any Soviet threat to the vital Persian Gulf. The Cold War was on once more. [283]

President Reagan continued these policies of military strength and tough diplomacy against the Soviets. His rhetoric, and his long-standing visceral opposition to Communism more broadly, helped change the tone of the Cold War. Carter promised opposition to further Communist expansion. Reagan wanted to see Communism's collapse. He called the Soviet Union an "evil empire," and later declared that "Marxism-Leninism" was destined for "the ashheap of history." He refused, in 1981 at least, to meet Soviet requests for arms reductions. By the mid-1980s, the Soviet economy could no longer support the country's competition with the West. When Reagan announced plans for an expensive new space-based missile defense system termed "Star Wars," or officially the Strategic Defense Initiative (SDI), Soviet leaders knew they could not afford to keep pace. Most analysts believed SDI to be technically infeasible. The very fact that Washington seemed willing to spend the money to find out, coupled with their inability to do the same, pushed the realization among Soviet leaders of the necessity of change. They had by 1985 only fifty thousand computers in their entire country, compared to America's thirty million, and youthful reformers such as the energetic Mikhail Gorbachev began a series of radical changes of the Soviet system, with *glastnost* (openness to the West) and *perestroika* (economic reconstruction). Reagan wanted more. "Mr. Gorbachev," he declared in Berlin while overlooking the most visible symbol of the East-West divide, "tear down this wall." Gorbachev could not, at least not without prompting a right-wing revolt at home. The forces he set in play, however, those of change and of modernity, swept through Europe. In November of 1989, Berliners both East and West tore down the wall that had divided them for more than a generation. [284]

The Cold War was not officially over—it had never officially begun—but it was clearly at an end. It would be up to democratic reformers such as Russian President Boris Yeltsin (Gorbachev was a reformer, but he was no democrat) to move the remnants of the Soviet Empire into a new day of cooperation with its neighbors and the world. Political scientist Francis Fukuyama famously declared the progress of history to be finally at an end. With the close of the Cold War, "political liberalism" had finally won out over totalitarianism. The stability of democracies would thereafter reign. As events have sadly shown, the post-Cold War world did not bring the stability promised, leading some pundits to publicly long for the security the bipolar Cold War system offered. The threat of global thermonuclear war might have lessened after 1991, the very threat Minuteman was originally developed to counter and deter. But the world may be no less safe for it. To the question of who "won" the Cold War, while most evidence points to the West, as responsible historians we can only answer as Chinese Prime Minister Zhou Enlai did when asked the significance of the French Revolution: "it is too soon to tell." Mining

Instead of just being happy with the military construction contracts, Kiewit Sons' broadened their scope and started getting involved in mining. It was an offshoot to their military ventures, since coal from the Big Horn Mine in Wyoming was needed at the Hanford Project in Washington State. This was were the top-secret Manhattan Project was carried out.

https://sah-archipedia.org/buildings/OR-01-057-0011

Hangar B was the first hangar erected by the U.S. Bureau of Yards and Docks with the Sound Construction and Engineering Company; its construction lasted from October 1942 to mid-August 1943. Meanwhile, the first airship arrived in February 1943, but, with no hangar to protect it, the blimp was shredded in a late March coastal storm. The second structure, Hangar A, was built much more rapidly, in just 27 days (July to August 1943) since the engineering challenges had been sorted out in the construction of Hangar B. The hangars each required 2 million board feet of lumber, most of it from Oregon, which was supplied by 50 local lumber mills. Even the gutters and downspouts were wood, and as a result more than 2,000 tons of steel were conserved per hangar.

KIEWIT COMPANY HISTORY TIMELINE

1884

Kiewit Corporation traces its history to 1884, when Peter and Andrew Kiewit formed Kiewit Brothers, an Omaha, Neb., masonry contracting partnership.

What began in 1884 with two hardworking brothers has grown into a construction, mining and engineering powerhouse.

1889

In 1889, Kiewit Brothers was awarded its largest masonry contract, the 7-story Lincoln Hotel.

1900

The brothers ventured into general contracting in 1900 with construction of the Bekins Warehouse.

1904

They dissolved their partnership in 1904, and Peter continued the business as a sole proprietor.

1912

In 1912, two of his sons, Ralph and George Kiewit would join their father as partners in the firm.

1914

The senior Pieter Kiewit passed away in 1914, and his two sons, Ralph and George Kiewit, renamed the company, Peter Kiewit Sons.

1919

1919 After attending Dartmouth for a year, Kiewit returned to Omaha in 1919 to work at his family s general contracting business.

1920

By 1920, the youngest of the Kiewit children, also named Peter, left Dartmouth College in his freshman year and joined the company as a foreman.

Meanwhile family members began to pull out of the company, a move begun by George Kiewit in the mid-1920s.

1924

In 1924, the company reached the 40-year mark and landed its first million-dollar contract the 10-story Livestock Exchange Building in the South Omaha meat-packing district.

Also in 1924, George Kiewit left the company and Ralph and Peter Kiewit jointly managed the company.

1930

In 1930 Peter Kiewit suffered the obstruction of a blood vessel resulting from the chronic inflammation of his veins--a condition called phlebitis.

Around 1930, many of his family members began leaving the business, and it appeared that the Kiewit legacy nearly 50 years in the making was coming to an end.

1931

When Ralph Kiewit moved to California in 1931, Peter dissolved the family firm and reorganized as Peter Kiewit Sons', Co.

1939

Starting in 1939, war construction started to build, and Kiewit successfully bid on a 7.5 million government contract to build 760 barracks and related facilities in Fort Lewis, Washington.

1944

1944 While Peter constantly strove to educate himself and develop better business practices, he similarly pushed his employees to learn and grow.

His process of building better men and women through company training sessions formally began in 1944 with the first annual meeting of Peter Kiewit Sons . Peter said, Better trained men will perform more and work better and will do so in a safer manner.

1949

1949 In 1949, Peter purchased Pawnee Springs Ranch near North Platte, Nebraska, the second ranch he came to own in addition to the X-Bar-X in northern Wyoming.

1950

In 1950 the United States Corps of Army Engineers approached Kiewit for assistance in a joint venture to construct bomber and housing installations in Greenland.

The 1950 s saw many other development projects in which Kiewit was actively engaged.

1952

In 1952, the Atomic Energy Commission awarded Kiewit the contract for the construction of the 1.2 billion Gaseous Diffusion Plant at Portsmouth, Ohio.

1954

1954 Because of Peter Kiewit s deep commitment to his community, he served on the Ak-Sar-Ben board of governors for 16 years, beginning in 1954.

1958

In 1958 the United States Army awarded Kiewit a 5 million contract to build Alaska's first nuclear facility.

1959

1959 In Omaha, as the city s downtown waned, Kiewit became instrumental in revitalizing the area, serving on the Omaha Development Council and the Omaha Industrial Foundation.

1961

The United States Air Force awarded the company a 68 million contract in 1961 for the construction of Minuteman intercontinental ballistic missile launch bases near Minot Air Force Base in North Dakota.

1965

1965 Later in his life, Peter became more philanthropic and donated millions of dollars to charities and institutions that he admired.

One of his first sizeable public donations went to Creighton University in 1965 for the construction of Kiewit Hall, a women s dormitory.

1967

1967 Recognizing Peter s focus on workplace safety, the National Safety Council awarded Peter Kiewit Sons its highest accolade, the Award of Honor, based on the company s record of 21 million man-hours of safe work.

1969

In 1969, Peter turned the presidency over to Bob Wilson, and Peter remained as chairman.

1970

In the 1970 s, Kiewit became one of Canada s leading contractors through its participation in the building of the dam and powerhouse facilities on the La Grande and East Rivers in Northern Quebec, as part of the massive James Bay hydro-electric project.

1971

I**n 1971 the company was awarded a 50 million contract by the United States Army to begin preliminary work on building facilities at Malmstrom Air Force Base in Montana for the Safeguard anti-ballistic missile program.**

He was chairman of the building committee for the latter, and saw to the construction of the original hospital building, which was dedicated in 1971 before an audience that included President Richard Nixon and California Governor Ronald Reagan.

1976

The company gained an even greater share of the coal market in 1976, when Black Butte Coal Co., a joint venture with Rocky Mountain Energy, landed contracts to supply three million tons of coal annually to Idaho Power Light Co. for 25 years, and to Commonwealth Edison Co. for 20 years.

1976 The Jesuit community at Creighton awarded Peter its Manresa Medal for inspirational and enduring achievement and the University of Nebraska Medical Center presented Kiewit with its Distinguished Service to Medicine award.

1978

In 1978 Kiewit won yet another contract from the army for 245.3 million to build a powerhouse at the Bonneville lock and dam in Washington State.

1978 Peter was recognized as an Honorary Founder of Creighton University, only the second time in the school s then 100-year history that the honor was given.

1979

Peter Kiewit Foundation opened its doors in 1979 with a 150 million endowment.

Black Butte, a southwest Wyoming coal mine, began production in 1979.

In November 1979, Peter Kiewit died as a result of complications following the removal of a tumor on his left lung.

1983

By 1983, however, high interest rates had begun to severely limit the number of large public building projects.

1984

By the time Kiewit celebrated its centennial in 1984, the company had district offices throughout the United States and Canada, and was performing nearly all types of construction work.

1985

Kiewit initially owned 80 percent of Continental, but fully acquired the company in 1985 after purchasing Murdock's stake.

1986

After enlarging the breadth of its investments, the company was reorganized in 1986 to better reflect the more diverse nature of its businesses.

1991

Kiewit found a buyer for Continental Can in 1991, and the company returned to a more concentrated pursuit of its specialty--construction.

1993

By 1993 the average construction contract was for 5.3 million, with a typical year bringing in 200 to 300 contracts.

2004

Bruce Grewcock, Kiewit s president and CEO, has steered the company to excellence since 2004.

2010

In 2010, it partnered with the New York State Office of Cultural Education to establish the New Netherland Research Center, with matching funds from the State of the Netherlands.

2012

In 2012, Grewcock was chosen as chairman of the board.

Kiewit had 2012 revenues of more than 11 billion and consistently ranks among the top five contractors by Engineering News-Record.

2018

Kiewit had 2018 revenues of 9 billion and consistently ranks among the top ten contractors by Engineering News-Record.

Founded

1884

Headquarters

Omaha, NE

Minuteman at Minot Air Force Base

Built in the mid-1950s to host a Semi-Automatic Ground Environmental (SAGE) complex and Air Defense Command fighter aircraft, Minot became a Strategic Air Command base on July 1, 1962, pending the imminent activation of Minuteman I-B missile launchers.

The Corps of Engineers Ballistic Missile Construction Office (CEBMCO) oversaw the construction of the **150 silos and 10 launch complexes spread over a 12,000-square mile area. The prime contractor was the Peter Kiewit Sons' Company, which received the contract on December 22, 1961, with a bid of $67.8 million. At the peak of construction, Kiewit brought in 6,000 men with 1,100 vehicles and 115 cranes to ensure on-time completion of the contract.** Relations between management and this work force were amicable as there were only two work stoppages that cost 58 man-days lost.

To manage the project, CEMBCO used a "critical path" method, which is essentially a daily charting of progress geared to project future needs. However, despite improved management techniques, CEMBCO and the contractors faced challenges from the severe weather and logistics support for the remote locations. Recordbreaking spring rains turned roads and work sites into quagmires, making excavation and transport dangerous. Severe winter cold with temperatures as low as -35 F tested worker endurance. In the autumn, dust storms made travel hazardous.

Despite these challenges, Peter Kiewit Sons' Company used accelerated construction procedures and completed the project 51 days ahead of schedule. Two workers died in construction-related incidents and there were 36 disabling injuries. Four private citizens died in various traffic accidents with project construction vehicles.

With construction under way, the Air Force activated the 455th Strategic Missile Wing and component 740th Strategic Missile Squadron on November 1, 1962. During the following 2 months, the 741st and 742nd Strategic Missile Squadrons administratively came into existence.

To preserve the continuity of units with distinguished histories, on June 25, 1968, the 455th Strategic Missile Wing was redesignated as the 91st Strategic Missile Wing. The 91st had organizational roots dating from World War II and had gained recent fame as a B-52 wing operating over Vietnam.

The first Minuteman III missile to arrive in the field was accepted by the 91st Strategic Missile Wing on April 14, 1970. The following August, the first Minuteman IIIs were placed on alert status. By December 1971, the switchover to the new missile was completed.

In addition to Minuteman ICBMs, Minot AFB hosted another type of strategic missile. Assigned B-52H bombers were modified to carry Air Launched Cruise Missiles (ALCMs).

[**Walter Scott Jr. (born 1931)**] was first elected to the Peter Kiewit Sons' Incorporated board in 1964. In 1979, he was elected president. When Peter Kiewit died later that same year, Scott was selected to succeed him as chairman.

Expansions

In 1963, Peter Kiewit bought the *Omaha World-Herald* to keep it locally owned. Under the terms of his will, the employees bought the paper in 1979.

Starting in 1985 (Kiewit built MFS in the early 1990s; Level 3 was built in the 1997 to 1999 circa), Kiewit also constructed a nationwide fiber optic network. This network was later spun off as Level 3 Communications, which became the formal successor corporation to the original Peter Kiewit Sons'.

Peter Kiewit Sons firm announces reorganization

OMAHA (AP) — Officials at the Peter Kiewit Sons' Inc. construction company have announced a corporate reorganization that creates two classes of stock and combines businesses.

Officials said the reorganization created Class C stock, which tracks the company's construction and mining businesses. Another class — Class D — pertains to the company's other businesses, including telecommunications and electrical energy.

Walter Scott Jr., Kiewit's chairman, presented the new structure to stockholders at the annual meeting Friday in Omaha. Stockholders of the privately held firm approved the reorganization in December, Kiewit officials said.

Under the reorganization, Scott remains president and chairman of Peter Kiewit Sons Inc. and also will serve as president of Kiewit's Diversified Group, which includes the telecommunications and energy businesses, the company said.

The company's construction and mining businesses are combined under the new structure.

Charles H. Campbell, a Kiewit executive vice president and former president of the construction group under the old structure, was promoted to vice chairman of the parent firm. He also was named chairman of the Construction and Mining Group, the company said.

Kenneth E. Stinson, president of the mining group under the old structure, was named president of the construction and mining segment.

James Q. Crowe, who was division manager in the old construction group, will serve as president of Kiewit's Telecommunications Group, the company said.

Kiewit had construction and mining revenues of about $2 billion in 1991, company spokesman Brad Chapman said Friday. He declined to say what the firm's total revenue was.

The company had $5.1 billion in revenue in 1990, according to Fortune magazine.

Kiewit was under contract to build more than 700 projects in 1991. The company said it shipped about 17 million tons of coal.

Kiewit operates construction offices through the United States and Canada. The company builds major projects in the power, commercial building and telecommunications industries.

The company has 2,900 salaried, full-time employees and employs 20,000 to 25,000 independent craftsmen each year, Chapman said.

Affordable housing in reach

Nebraska companies announce equity fund

BY ED RUSSO
Lincoln Journal

Warren Buffett of Omaha, the country's richest man, joined Gov. Ben Nelson, Lincoln Mayor Mike Johanns and Lincoln business executives today to announce a fund intended to build more affordable housing in Nebraska.

Warren Buffett

Buffett's Berkshire Hathaway Inc. and eight other corporations have contributed $5 million to the Equity Fund of Nebraska, which finances affordable-housing projects. In return, the fund provides the companies with federal tax credits granted over 10 years.

"It's the best of all worlds," Buffett said at a news conference in the Governor's Mansion.

Johanns and Nelson praised Buffett as well as Orrin Wilson of FirsTier Bank-Lincoln and John Haessler of Woodmen Accident and Life, which has contributed to the renovation of the President and Ambassodor building near the Capitol for low-income housing.

So far the 1993 fund has agreed to contribute $2.9 million to help pay for affordable housing ventures under way in Lincoln. One, the Charles Senior Housing Limited, is renovating housing at 1936 and 1938 F St., and building new housing at 1933 G St. The Indian Center is using the fund to help pay for an apartment project at Southwest Ninth and A streets.

Besides Berkshire Hathaway these other companies participated in the 1993 Equity Fund: Kiewit Diversified Group Inc., FirsTier Financial Inc., Guarantee Mutual Life Co., Mutual of Omaha, Norwest Bank Nebraska, Commercial Federal Bank, Central States Health and Life Company.

"The Nebraska business community has responded to this opportunity as we have expected them to," Nelson said.

Speaking to Buffett, Johanns said, "It's gotten around that you have made a wise investment here and there and that helped us sell the program."

Officials want companies to invest in the 1994 fund.

Affordable housing is one of Nebraska's most pressing needs, Nelson said. Studies show that one in 50 Nebraska families lives in substandard or overcrowded conditions or pays more than 30 percent of its income for housing. Affordable housing for moderate to low-income people is especially needed in Kearney, Aurora and Thurston County as well as Lincoln and Omaha.

National equity funds were created after the passage of the 1986 federal tax bill. Buffett said Berkshire Hathaway has contributed between $2[illegible] million and $30 million to such funds which help build affordable housing in various cities around the country.

For information about how to contribute to the 1994 Equity Fund of Nebraska, call executive director Jim Rieker at 346-2577, or write the Equity Fund of Nebraska, Suite 930, 1650 Farnam St., Omaha, NE 68102.

Centex stock surges after takeover bid by MFS

By Karen Padley
Bloomberg Business News

SAN FRANCISCO — Centex Telemanagement Inc., one of the first companies to manage local and long-distance telephone services for smaller businesses, saw its shares more than double yesterday after MFS Communications Co. offered to buy the company for $9 a share cash.

Centex stock gained $5.62½ to close at $10.50. More than 12.6 million of the 17.7 million shares outstanding changed hands, making it the most active Nasdaq issue.

MFS Communications, based in Omaha, Neb., announced its offer late Tuesday, saying it had been rebuffed by Centex's board. It already owns 8.4 percent of Centex stock.

Centex said yesterday it is considering the offer and will respond within the next 10 business days.

Analysts applauded the proposed merger, saying it would be a good fit. Both offer similar products for small and medium-sized businesses, although MFS Communications depends more heavily on networks and Centex on services.

A possible 'coup'

MFS Communications stock closed up $4.37½ at $35.12½. Volume was 1.45 million shares, almost three times the three-month daily average.

"If they get Centex, it will be a coup for them," said Ronald Altman, an analyst with Furman Selz, New York. "The combination makes an enormous amount of sense as competition increases in the local markets."

MFS was spun off in May 1993 from Kiewit Diversified Group Inc., a unit of closely held Peter Kiewit Sons' Inc. It benefited from a September 1992 ruling by the Federal Communications Commission that opened local telephone service to competition, ending the monopoly enjoyed by regional telephone systems.

The company lost $16 million, or 30 cents a share, in 1993. It is expected to keep losing money as it builds fiber optic networks in 65 cities over the next three to five years.

"MFS is making significant capital improvements in those networks so the more they add customers, the quicker they reach profitability," said Jacqueline Popp, a Duff & Phelps Corp. analyst.

Altman said two thirds of Centex's 11,000 customers are located in California, which would give MFS the kind of scope and scale it will need.

"This will accelerate MFS' move toward profitability," Altman said. He estimates MFS with Centex could break even by the end of 1996 instead of late 1998.

$5.1 million reserve

Centex, founded in 1983, has been publicly traded since 1987. It provides local, long-distance, conference calling, voice mail and other services for small to medium-sized businesses. It does not provide long-distance service directly, as MFS does, but uses various carriers.

The company set aside a $5.1 million reserve in the fourth quarter to restructure its operations, accelerate sales and improve efficiency. Centex last week laid off 18 people from its headquarters.

Hawaii buying ethanol-powered cars

❑ State coalition backs grain-based fuel for new cars

By Steve Kline
Associated Press

OMAHA, Neb. — Ethanol-powered cars are on a roll.

Representatives from Hawaii and the other 18 states of the Governors' Ethanol Coalition meeting here announced a major purchase of such cars, Nebraska Gov. Ben Nelson said yesterday.

Orders for cars that can run on mixes of up to 85 percent ethanol and 15 percent gasoline might surpass 500 this year, he said.

By 1996, Nelson said, local, state and federal governments are expected to order more than 2,500 of the cars.

Ethanol derived from corn and other grains is often used as a fuel additive.

Nelson said the General Services Administration is purchasing 250 so-called E85 Ford Tauruses, the maximum number available from the manufacturer.

Nelson said ethanol interests expect to win a court battle over an Environmental Protection Agency rule that would benefit ethanol by requiring it in new mixes of gasoline used in the nation's most-polluted cities.

The oil industry has filed a lawsuit alleging that the EPA is going beyond the 1990 Clean Air Act by specifying a fuel additive, and a federal appeals court has blocked implementation of the rule.

Nelson said that ultimately, farm interests and oil interests will have to work together to resolve their differences.

"The Congress has continued to support this (the EPA rule). So has the White House. We'll play an important role in reformulated fuels," Nelson said.

In addition, Nelson announced that the federal government had agreed to fund, in part, a $1.3 million effort to add up to 40 publicly accessible E85-vehicle fueling sites throughout the Midwest.

Nelson said up to $510,000 will come from several government programs, with the remaining $810,000 coming from private sources.

Nelson said state and national groups already have pledged $285,000.

The effort would recondition existing fuel storage tanks or install new ones at filling stations in states with a large number of the ethanol-powered cars.

The most likely states are Nebraska, Iowa, Colorado, Illinois, Indiana, Minnesota, Missouri and Wisconsin, Nelson said.

In addition to those states, the ethanol coalition has representatives from Arkansas, Hawaii, Kansas, Kentucky, Michigan, Montana, New Mexico, North Dakota, Ohio, South Dakota and Texas.

Also during yesterday's news conference, retired Air Force Gen. Lee Butler, former commander of the Strategic Air Command (now the Strategic Command), announced the establishment of a company called Kiewit Fuels.

It is a newly formed unit of Kiewit Diversified Group of Omaha.

The company will merge with Sunthetic Energy of America, of Phoenix, which owns a patented process for making fuel alcohols and their derivatives.

The coalition meeting ends today.

1998 (Jan 20) - "Kiewit Diversified" changed it's name to Level 3

Full page : [HN01CL][GDrive]

Fremont Tribune (Fremont, Nebraska) • 20 Jan 1998, Tue • Page 12

Kiewit Diversified plans name change, move to Denver

OMAHA (AP) — Kiewit Diversified Group has chosen Denver as the site of a new Internet-based company expected to create up to 3,000 jobs.

The company made the announcement Monday. It said it would not move until it receives word from the Internal Revenue Service on whether the company's split from Peter Kiewit Sons can be tax-free.

Kiewit Diversified is a subsidiary of Peter Kiewit Sons, an Omaha-based construction and mining company.

The company announced in December it would start the Internet-related business elsewhere because of the difficulty of attracting computer nerds to Omaha.

The IRS decision is expected before the end of June. The relocation will affect 30 to 40 Kiewit Diversified executives. No other Kiewit operation will be affected.

Kiewit Diversified also said it is changing its name to Level 3 Communications to better reflect the new venture.

Level 3 Communications will focus on building a nationwide, Internet-based network to compete with local and long distance telephone systems, the company said. Long-range plans include international competition.

Areas under consideration for the new headquarters were Dallas, northern Virginia and the Silicon Valley in California.

[HN01CM][GDrive]

1998 (Jan 21) - "Peter Kiewit Sons to Build National Fiber Optic Network"

By Seth Schiesel / Source : [HN00ZF][GDrive]

Adding to the growing list of companies that are building new national communications networks, Peter Kiewit Sons Inc. has said that it intends to spend up to $3 billion over the next three years to build a 20,000-mile web of fiber optic cable.

The system, which the company wants to complete by 2001, would be the first national fiber optic network based on Internet technology rather than on standard telephone technology. If the Internet technology works as predicted, it could allow Kiewit to charge prices for voice and data communications much lower than those of its competitors while maintaining healthy profit margins.

Kiewit plans to sell access to its network only to business customers. Most of those would be small and medium-sized companies, but some could be upstart long-distance carriers that would resell time on the Kiewit network to consumers.

On Monday, the Kiewit subsidiary that intends to build the network, **Kiewit Diversified Group Inc.**, announced that it had changed its name to [**Level 3 Communications, Incorporated**]. Level 3 is led by a team of executives who used to run the [**MFS Communications Company, Incorporated**], the alternate local telephone carrier acquired in 1996 by Worldcom Inc. for $14 billion.

The move by Kiewit, a private company based in Omaha that has its primary operations in construction and mining, brings to four the number of companies building new national communications networks. Kiewit joins IXC Communications, the Williams Companies and the Qwest Communications subsidiary of the Anschutz Corporation. Established long-distance carriers like the AT&T Corporation also spend billions each year upgrading their systems.

But Level 3's network would differ from the others in its reliance on Internet Protocol, or I.P., technology. I.P. can allow networks to be used more efficiently but can also be less reliable than traditional networks. Traditional networks generally allow voice and data messages to be transmitted in one continuous chunk. I.P. networks break messages into small packets that are each sent independently to their destination.

"I.P. is ready for prime time," said [**James Quell Crowe (born 1949)**], Level 3's chief executive, who was MFS's chairman. He said, however: "With today's technology, I.P. is fine for anything that's not timing-sensitive, like data or fax. Anything that's timing-sensitive, primarily voice and video, isn't handled very well."

But Mr. Crowe said that advances in the technology over the next few years would allow Level 3 to offer voice quality equal to that of more traditional systems.

Mr. Crowe said that Level 3 had about $2 billion in cash but that it was confident it could raise the remainder necessary to complete its network.

STATE OF WASHINGTON, County of Whatcom } ss.

I Hereby Certify, That on the 15th day of September in the year of our Lord one thousand eight hundred and ninety seven at Mec Whatcom in the County of Whatcom and State aforesaid, I, the undersigned, a Minister of the Gospel by authority of a license bearing date the 15th day of September A. D. 1897, and issued by the County Auditor of Whatcom County, did on the 15th day of September A. D. 1897, join in lawful wedlock John Kildall of the County of Whatcom State of Washington, and Miss Christina Johnson of the County of Whatcom State of Washington.

IN PRESENCE OF

Etta Kildall } Witnesses.
Simon Kildall }

John Kildall Groom.

Christina Johnson Bride.

Walter L. Bramblett
Minister of the Gospel

Filed for Record, this 9th day of October 1897

By Deputy. J.S. Appleby Clerk.

WORLD'S RECORD OF FISHING AND FISH-PACKING BEATEN BY PUGET SOUND SALMON-CATCHERS

Last Year the Combined Pack of the Puget Sound and Gulf of Georgia Canneries Was 265,000 Cases—Already This Season Nine Canneries in One County Have Packed 589,000 Cases, and All Are Still Working at High Pressure.

"Only Chinamen Were Employed in the Work and They Looked Like Blood-Smeared, Yellow Devils."

In a Puget Sound Salmon Cannery.

BY RUDYARD KIPLING.

Only Chinamen were employed on the work, and they looked like blood-besmeared yellow devils as they crossed the rifts of sunlight that lay upon the floor. When our consignment arrived, the rough, wooden boxes broke of themselves as they were dumped down under a jet of water, and the salmon burst in a stream of quicksilver. A Chinaman jerked up a twenty-pounder, beheaded and detailed it with two swift strokes of a knife, flicked out its internal arrangements with a third and cast it into a blood-dyed tank. The headless fish leaped from under his hands as though they were facing a rapid. Other Chinamen pulled them from the vat and thrust them under a thing like a chaff-cutter, which, descending, hewed them into unseemly red gobbets fit for the can.

More Chinamen, with yellow, crooked fingers jammed the stuff into the cans, which slid down some marvelous machine forthwith, soldering their own tops as they passed. Each can was hastily tested for flaws, and then sunk with a hundred companions into a vat of boiling water, there to be half cooked for a few minutes. The cans bulged slightly after the operation, and were, therefore, slidden along by the trolleyful to men with needles and soldering irons, who vented them and soldered the aperture. Except for the label, the "Finest Columbia Salmon" was ready for the market. I was impressed not so much with the speed of the manufacture as the character of the factory. Inside, on a floor ninety by forty, the most civilized and murderous of machinery; outside, three footsteps, the thick-growing pines and the immense solitude of the hills. Our steamer only staid twenty minutes at that place, but I counted two hundred and forty finished cans made from the catch of the previous night ere I left the slippery, blood-stained, scale-spangled, oily floors and the offal-smeared Chinamen.

NEW WHATCOM, Wash., August 29.—All records of fishing and fish-packing, in all the world's history, have been overwhelmingly eclipsed by the salmon canneries of Puget Sound and the Gulf of Georgia during the past six weeks.

The record of any single cannery for a single year has been distanced within six weeks by two different canneries in Whatcom county this season, and half a dozen traps have outdone any previous record of trap-fishing.

Last year the combined pack of the Puget Sound and Gulf of Georgia canneries was 265,000 cases.

Already this season nine canneries in Whatcom county alone have packed 589,000 cases—and the high tide is still keeping all available help busy at all the canneries and traps both day and night! Here are the figures showing the pack and put-up July 3d to August 23d inclusive:

Companies—	Cases.
Pacific-American Fisheries Co., Fairhaven	184,000
Alaska Packers' Association, Blaine	125,000
Alaska Packers' Association, Point Roberts	65,000
Young & Williams, Blaine	24,000
Ainsworth & Dunn, Blaine	58,000
Carlisle Canning Co., Village Point	36,000
Aberdeen Packing Co., Fairhaven	45,000
Fairhaven Canning Co., Fairhaven	40,000
Astoria and Puget Sound Co., Fairhaven	12,000
Total cases packed	589,000

On August 9th the Pacific-American Cannery received 130,000 fish, averaging seven pounds each dressed—about 400 tons of salmon in one day at one cannery—enough to load an ordinary freight train of twenty cars, twenty tons to the car.

Last Sunday, August 20th, this cannery received 115,000 salmon, and the rule has been, since July 7th, over 50,000 a day.

It is difficult to comprehend the enormousness and tremendous results of this marvelous run of salmon. Consider that within six weeks' time these nine canneries have packed 589,000 cases, which, at the lowest market price f. o. b., $4 50, represent a cash value of $2,650,500.

These 589,000 cases contain forty-eight one-pound cans each; therefore they weigh 28,272,000 pounds, exclusive of cases, or 14,131 tons, and it would require a freight train four and a half miles long to carry them all away, each car carrying twenty tons.

Had the serpent shunned the Garden of Eden and these 589,000 cases of salmon been available to Adam and Eve, the latter could have enjoyed a can of salmon three times a day for over 25,819 years!

Or, each man eating one can a day, an army of 100,000 men could eat from this tremendous pile for nine months and two weeks, and then have 75,000 cans left to gamble for!

Placing these cans end to end, they would make a solid, glittering band of sealed salmon over 2,068 miles in length.

But the canned pack is only the principal feature of the output of these fisheries, and the amount of energy set in motion when the silvery army comes. There are in connection several box factories, many cooper shops, a sheet-metal works employing over 100 hands, two fertilizer and fish-oil factories, several salting and pickling enterprises, can factories, ice factories, cold-storage warehouses and three or four fresh-fish shipping establishments.

In the nine canneries 1,956 persons are employed. The auxiliaries, such as can factories, cooper shops, etc., employ 600 more, and the traps, steamers, tugs and scows add about 700, making a total of 3,256 persons, of which over 1,000 are Chinamen and the balance are whites of all sexes from six to sixty years old.

Aside from these are about 1,000 gill-net fishermen, making a grand total, at a conservative estimate, of 4,250 persons employed in the fisheries of this county, which four years ago had but one small cannery—the A. P. A. Cannery at Point Roberts.

Sockeye salmon have commanded a higher price to the fishermen this year than ever before, ranging from 12 cents to 22 cents each. This is the great trap-fishing region, and 140 traps, the average cost of each of which is about $4,000, are operated in this county. Some of these have been unsuccessful this year. The Kiddall trap at Cherry Point, Gulf of Georgia, heads the successful ones, having taken 220,000 fish this season. Several others have done nearly as well.

The Pacific-American Fisheries Company, organized last March with $5,000,000 capital by prominent Chicago men, with Mr. Cudahy, the great meat packer, as President, has simply astonished old-time salmon men of Puget sound with its new methods of handling the fish-packing business. This company was no sooner afloat than it proceeded to buy up all the available trap locations in this region, securing forty-six of them for $720,000 cash. Three canneries were also absorbed, with many fishing vessels, and an island in the channel of Bellingham bay to be used as a rendezvous for trapmen and web-preparers.

Early in the spring the company established a shipyard at New Whatcom, employing about 200 men from April 15th till July 4th, paying out over $15,000 in wages. This shipyard built twenty-two scows, 16x50 feet, value $700 each, total value $15,400; twelve scows 8x30, $275, total value $3,300; six dories, 8x30 feet, $150, total $900; two steam piledrivers, 24x65 feet, guns 75 feet high, 7,000-pound hammers, value $6,000 each, total $12,000.

The shipyard razed up over 500,000 feet of lumber. The wages paid ranged from $1 50 to $5 per day.

But the most gigantic evidence of the revolutionary methods of this new force in our fisheries is the great cannery at Fairhaven. When the Alaska Packers' Association of San Francisco three years ago built its famous cannery at Blaine, having a capacity of 4,000 cases per day, the old-time packers of the Pacific Coast shook their heads dubiously and remarked that it would be impossible to operate so tremendous a concern at a profit. It was far the largest fish-packing establishment in the world. But when the Pacific-American Company required two or three acres for its new cannery buildings at Fairhaven and put up a main cannery building 350 feet long and 200 feet wide, and set machinery for a capacity of 6,000 cases a day, the old-time canners "had a fit."

Such a thing as employing from 500 to 600 persons within the walls of a single cannery was unheard of and, said to be impracticable; but it wasn't and has proved a wonderful success in a season of unprecedented rushing. Aside from its enormous pack, this great establishment ships from one to three carloads per day of fresh fish on ice to the great cities of the East, each car holding 26,325 pounds according to the average up to date; and as fresh iced salmon wholesales at 15 cents a pound in New York, a carload is worth $3,949 95, or about $2,000 net here.

The salting and pickling department of this big plant employs 200 hands and is operated with the greatest expediency day and night. No Chinamen are engaged in this work, although over 250 are employed in the cannery. Several methods of salting are employed, but the principal process is equipped with three enormous vats of timber, each vat being six feet deep, eight feet wide and ten feet long. The salmon are dressed, beheaded and disentrailed, and thrown into the vats in layers, a thick coat of salt marking the layers. The fish are tamped in solid, the meat being pressed in so that the interstices will admit no air.

The P.-A. F. Co. has orders ahead for an extensive trade with the Japanese. The little Orientals require that salmon salted for them shall not be beheaded and that the fish must be allowed to fairly enter a state of decomposition or decay before salt is applied; then they must be dry salted and packed in barrels.

The Puget sound salmon pack will reach very close to a million cases this year, and the industry is still considered in its infancy. The eight new State salmon hatcheries will add about 75,000,000 young salmon to the storehouse of the Pacific next season, and the hope of this mighty industry rests with them.

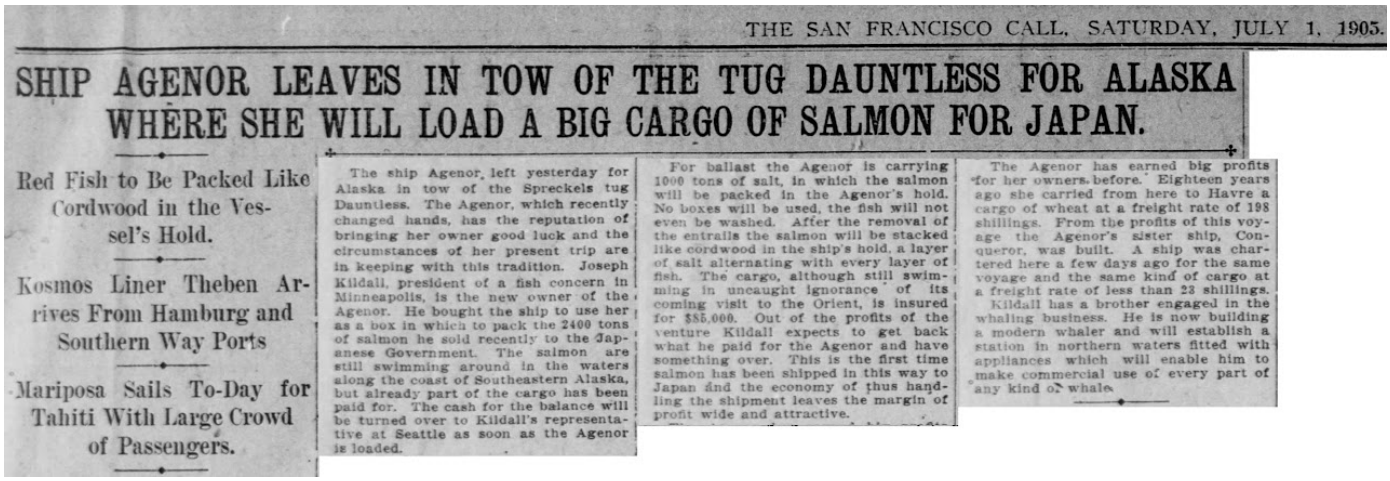
SCHEDULE SHEET NO.

[HS003U][GDrive]

1905 (July 1)

Full newspaper page : [HN019U][GDrive]



THE SAN FRANCISCO CALL, SATURDAY, JULY 1, 1905.

SHIP AGENOR LEAVES IN TOW OF THE TUG DAUNTLESS FOR ALASKA WHERE SHE WILL LOAD A BIG CARGO OF SALMON FOR JAPAN.

Red Fish to Be Packed Like Cordwood in the Vessel's Hold.

Kosmos Liner Theben Arrives From Hamburg and Southern Way Ports

Mariposa Sails To-Day for Tahiti With Large Crowd of Passengers.

The ship Agenor left yesterday for Alaska in tow of the Spreckels tug Dauntless. The Agenor, which recently changed hands, has the reputation of bringing her owner good luck and the circumstances of her present trip are in keeping with this tradition. Joseph Kildall, president of a fish concern in Minneapolis, is the new owner of the Agenor. He bought the ship to use her as a box in which to pack the 2400 tons of salmon he sold recently to the Japanese Government. The salmon are still swimming around in the waters along the coast of Southeastern Alaska, but already part of the cargo has been paid for. The cash for the balance will be turned over to Kildall's representative at Seattle as soon as the Agenor is loaded.

For ballast the Agenor is carrying 1000 tons of salt, in which the salmon will be packed in the Agenor's hold. No boxes will be used, the fish will not even be washed. After the removal of the entrails the salmon will be stacked like cordwood in the ship's hold, a layer of salt alternating with every layer of fish. The cargo, although still swimming in unconscious ignorance of its coming visit to the Orient, is insured for $85,000. Out of the profits of the venture Kildall expects to get back what he paid for the Agenor and have something over. This is the first time salmon has been shipped in this way to Japan and the economy of thus handling the shipment leaves the margin of profit wide and attractive.

The Agenor has earned big profits for her owners before. Eighteen years ago she carried from here to Havre a cargo of wheat at a freight rate of 198 shillings. From the profits of this voyage the Agenor's sister ship, Conqueror, was built. A ship was chartered here a few days ago for the same voyage and the same kind of cargo at a freight rate of less than 23 shillings.

Kildall has a brother engaged in the whaling business. He is now building a modern whaler and will establish a station in northern waters fitted with appliances which will enable him to make commercial use of every part of any kind of whale.

CONSPIRACY

President of Kindall Fish Company is Arrested.

Minneapolis, Minn., Dec. 14.—Joseph H. Kildall, president and manager of the Kildall Fish company of Minneapolis, and president of the West Coal Commercial company of Alaska, was arrested today by United States Marshall Grimshaw on a warrant issued under an indictment returned by the federal government of Alaska, which charged him with being a party to conspiracy to evade the payment of taxes on calmon caught in Alaskan waters.

He appeared before United States Commissioner Howard S. Abbott, with Former Governor John Lind as his counsel. The hearing was postponed a week. The indictment alleges that the company, on Oct. 27, 1905, shipped 1,500 barrels of salmon to Yokohama without paying the tax. S. F. Kildall, H. C. Killam and M. B. Johnson are also named on the indictment.

Mr. Kildall declared later that as the salmon wa not packed in barrels it was not liable to the tax. Furthermore, he alleged that his company tendered $750 in payment of taxes which was refused as not due. Mr. Kildall's efforts will be directed towards avoiding a trip to Alaska to stand trial.

KILDALL CLEARED OF CONSPIRACY

Joseph Kildall was discharged from the charge of defrauding the government by United States Commissioner J. W. Marshall this morning. Mr. Kildall, the president of the West Coast Commercial company, was charged with having shipped a cargo of salmon in the Agenor from the Alaskan coast without paying the license tax which was required by law. His defense was that the cargo had been started before the passage of the law by congress.

In rendering a decision Commissioner Marshall said:

"I hold that there are not reasonable and probable grounds to believe the defendant guilty as charged in the indictment. The prima facie case made out by the indictment is overcome by the evidence of the defendant, corroborated by that of Judge Foot and the dispatches from the secretary of the treasury at Washington, D. C., directing that the ship Agenor be released, and which removal by authority of law could not be an overt act of conspiracy on the part of the defendant as charged."

P. C. KILDALL DEAD AFTER LONG STRUGGLE

P. C. Kildall, formerly in the mercantile business at Severance, died at Albuquerque, N. M., December 24th. Mr. Kildall was known to many Windsor people. We quote as follows from a Tacoma paper:

"Capt. Peter C. Kildall, one of the most widely known mariners of the North Pacific and prominently identified for more than fifteen years with marine transportation on this coast, died at Albuquerque, New Mex., last Tuesday, after a long illness.

"Capt. Kildall was known by nearly every steamship master on the coast and in Alaska and had many personal friends in the Puget sound trade. He was born in Norway, March 9, 1862, and came to Washington in 1887 He was a master mariner for over ten years.

"During the construction of the Pacific coast & Norway Packing Co.'s plant at Tonka, Alaska, which he was superintending, Capt. Kildall contracted a severe cold, which resulted in tuberculosis

"He was forced to resign as general superintendent of the company and went to Norway, where he spent a year in the mountains in an effort to regain his health. He then returned to this country,going to Chicago, where he entered the fish business. The Chicago climate was too severe and Capt. Kildall was forced to close up his affairs and seek a higher altitude in Colorado

"He entered the general merchandise business in Colorado, where he remained several years and was very successful. Last year Capt. Kildall sold his business interests in Colorado on the advice of his physician and again returned to Norway, but found no relief. He then went to Albuquerque, where he was taking treatment at a saniarium at the time of his death

"Capt. Kildall is survived by a wife, formerly Miss Anna Lind, of Tacoma; two children, Helen Kildall and Robert Kildall; a father, Michael Kildall; three brothers and three sisters, Simon F. Kildall, Joseph Kildall, John Kildall, Mrs. Mary Lee, of Bellingham; Mrs. Anna Cavender and Mrs. Marian Bordon, of Seattle.

"The body of Capt. Kildall reached Seattle yesterday, accompanied by his wife and two children. Funeral services were held Sunday."

On a Short Vacation

Mr. and Mrs. Joseph Kildall, and their daughter and son, Blanch and Harold and Miss Doris Cavender, a relative, arrived from Seattle on the Jefferson for a visit of ten or twelve days duration. They are visiting with Mr. and Mrs. John Kildall.

Mr. Joseph Kildall, besides being secretary and one of the directors of the Pacific Coast and Norway Packing Company, is one of the stockholders and organizers of the Kildall Fishing Company with its headquarters at Seattle. This company has been quite successful last season, in that, many fishermen have shipped direct to the company, and report having obtained satisfactory results. On this trip Mr. Kildall combines both business and pleasure, but with the family, it is all pleasure as Mrs. Kildall said.

LUNEVILLE IS VESSEL OF YACHT-LINE LINES

Product of Portland Shipyard Attracting Wide Attention in Port. Auxiliary Schooner is Handsome Craft, Staunchly Built and Lavishly Equipped

"In model and finish she is a yacht." Unusual interest is being displayed in marine circles in the arrival of the French auxiliary schooner Luneville in port, and the above is the unanimous expression of the large coterie of shipping men who have taken the opportunity of looking over the ship since her arrival from the Columbia River.

One of the twenty ships built by the Foundation Company at its Portland yard, the Luneville represents the finest type of marine architecture in auxiliary-powered vessels that ever entered this or any other port. Lying at her berth at the Outer Docks the vessel is the cynosure of all eyes, and she is declared by men who have sailed in all kinds of vessels to be the trimmest craft of her type afloat.

Capt. S. F. Kildall, inspector for the Bureau Veritas, and who has been in charge of all the ships turned out at the Foundation yard at Portland on their trial trips, is most enthusiastic about the Luneville, and this reflects his attitude regarding all the other ships of her class, forty of which have been built at the Portland and Tacoma shipyards of the Foundation Company.

Delighted With Ship.

Capt. Kildall came from Portland as master of the Luneville and he is delighted with the vessel.

"They are absolutely the finest ships I ever sailed in," commented Capt. Kildall, in discussing the Luneville and other ships of her type with a member of The Times staff to-day. "You couldn't get better-handling ships." "She is the most complete ship that money could produce and I may add that she is a credit to the Foundation Company, her builders."

Lieut. Albert F. Vaison de Fontaube, of the French Navy, and a member of the French High Commission in the United States and Canada, who went over the ship this morning in company with Paul B. Thompson, manager of the Foundation yards here, was highly pleased with the vessel and took a keen interest in her equipment. "She redounds great credit to her builders," remarked Lieut. Vaison de Fontaube. "I am well satisfied with her."

Built Last Year.

The keel of the Luneville was laid down at Portland on May 31, 1918, and on October 30 the vessel was launched. She was completely outfitted at the company's plant and ran her official trials on December 12. On her trials she averaged a speed of 10.36 knots. The Luneville is a five-masted vessel, schooner rigged. She is a vessel of 3,000 deadweight tons and 285 feet in length.

The Luneville is equipped with triple-expansion steam engines of 700 horsepower, having twin engines of 350 horsepower each. An inspection of the engine-room gives one the impression of the engineering appointments of a large liner.

On the run up the coast from the Columbia River the vessel reeled off ten and a half knots, and even when she ran into a snorting easterly gale off Cape Flattery she managed to knock off eight and a half knots. Speaking of the Flattery storm Capt. Kildall said: "She handled like a duck." The vessel came up under power, only the fore and stay-sail being used.

Coal is burned in the furnaces of the Luneville. The bunkers, with a capacity of 600 tons, are located aft.

Fine Accommodation.

In accommodation, for the officers and members of the crew, the ship excels anything in workmanship ever put into a cargo carrier. In addition to the captain's cabin and a spare room for his use, there are twelve splendidly fitted compartments for the use of the officers. These quarters line the port and starboard side right aft, the dining saloon being located amidships aft, with an up-to-date pantry conveniently adjacent. The woodwork in the officers' quarters is of polished oak and the furnishings are of the best procurable. Right abaft the stacks which parallel the "jigger" is located the engineer's quarters, which compare in every way with the officers' accommodation.

Crew in Clover

The members of the crew of the Luneville will be fortunate sons of the sea. The French crew has yet to arrive to take over the ship, but when they do they will have a pleasant surprise in store.

The sailors of a freight-carrier or passenger-carrier for that matter never saw better quarters than are provided on the Luneville. All the quarters are on deck right forward. In a house located between the "Fore" and "Main" is the galley, wonderfully equipped and with a tiled floor, and right alongside is the sailor's mess-room. Immediately forward of this is another house used as the sleeping quarters for the crew. Just think of it, these cabins contain iron berths, spring and sanitary mattresses and also an iron wardrobe to hold the men's personal effects. No ordinary sailor ever saw such snug quarters before.

Has Pretty Lines

The Lunville has pretty lines, resembling the lines of a pleasure yacht. The vessel is staunchly built and every part of her reflects thoroughness in construction.

To give an idea of the strength of her construction, the ship has four 20 by 20 keelsons, four 16 by 16 sister keelsons and two 14 by 14 bilge keelsons, all bolted through and rivetted clear to the keel. There is no doubt in the minds of anyone who understands ship-construction that the fastening and everything else about the Luneville has been thoroughly done.

No Vibration

No engines ever worked more smoothly, say her engineers. There was not the slightest evidence of undue vibration throughout the run up the coast. Neither did the vessel "Yaw," a fact especially remarked upon by her skipper.

In deck-equipment the vessel is perfect. The winches, anchors and other gear, including the hoisting of the sails, is all done by steam.

In addition to her port and starboard anchors the vessel carries a spare kedge and steam anchor. The lighting of the ship is all done by electricity. Electric lights are used for the binnacle, side-lights, search-lights, compass, and telegraph. The accommodation is elaborately fitted with electric-lighting fixtures. Everything to assist navigation is complete. There is auxiliary power forward for the operation of the gear when the main engines are shut down.

The five masts are each 132 feet in height to the truck, and the spread of canvass carried is estimated at 50,000 square yards. The running gear is of the best, being of the four-strand variety, Manila rope.

Brings Car Here.

Capt. Kildall and his wife, who came north with her husband, propose to make a tour of Vancouver Island before returning South. With this tour in view Capt. Kildall brought his automobile with him, the car being stowed on deck amidships.

C. W. Craig, who was assistant to Manager Paul Thompson at Portland, also came north on the Luneville, accompanied by his wife. Both Mrs. Kildall and Mrs. Craig signed on the ship's articles as stewardesses.

The members of the ship's crew were composed mostly of men in the employ of the Foundation Company at Portland. Capt. Skog is chief mate, and the engines are under the supervision of Chief Engineer Riley.

The Luneville, after completing the discharge of her 1,700-ton cargo, will proceed to Seattle to load for the voyage to France.

NO. 8

CITY MOURNS LOSS OF HUGH JAMIESON

Lynden Merchant Passes Away Suddenly Wednesday Morning; Funeral Services Sunday

Funeral services for the late Hugh H. Jamieson, who passed away suddenly at 1 o'clock Tuesday morning, will be held on Sunday at 1:30 p. m. at Knapp's Parlors, with the Rev. E. O. Grimes and the Rev. Herbert Jones of Ferndale, formerly of Lynden, officiating.

Bellingham Lodge No. 44, F. and A. M. will have charge of the services at the family plot at 3 p. m. at the Bay View cemterey in Bellingham, with an escort of the Knights Templar.

Mr. Jamieson retired Tuesday evening early in the best of spirits, whistling as he walked up the stairs. He seemed to be breathing heavily about one o'clock, and had passed away before a doctor could reach him.

Mr. Jamieson was born at Canterbury, New Brunswick Dec. 1, 1859. He came to Lynden 18 years ago, purchasing the Kildall Mercantile Company. Previous to that time, he had conducted a store at Clearbrook, and had been with the Washington Grocery Company of Bellingham for one year.

1922-08-10-the-lynden-tribune-city-mourns-loss-of-hugh-jamieson

In the passing of Hugh Jamieson, Lynden loses a stalwart friend. He had always been a leader in community activities, and contributed liberally to worthy civic movements. During the war, he served on various patriotic committees, doing his utmost as a loyal American.

During his long business career in Whatcom County, he made a legion of friends, to whom the news of his sudden passing came as a distinct shock. Mr. Jamieson was a member of Bellingham Bay lodge no. 44, F. & A. M.; Royal Arch chapter No. 12 and Hesperus Commandery No. 8, of Bellingham.

He is survived by his widow, Mrs. Cena Jamieson; one daughter, Reta, two sons, Ivan, of Lynden, and Cecil J., a lieutenant in the army at Fort Douglas, Utah; two sisters, Mrs. Prudence Keith, Rhinelander, Wis., and Mrs. Minnie Hay, Riverside, Cal., and five brothers, Clarence, of Ferndale; Charles of Stillwater, Minnesota; Andrew of Seattle; Will of Riverside, Cal., and James of Warner, Alberta.

Cecil Jamieson will arrive in Lynden Friday, and James Jamieson of Warner, Alberta, is expected here Saturday.

FUND CHECKUP ASKED IN MOTION

A court order permitting inspection of books of Pacific Electronics, including the personal account books of E. W. Johnson, partner in the firm, is asked by Washington Trust company in a motion filed in superior court yesterday.

It is asserted, in an affidavit supporting the motion, that Johnson may be diverting funds which should be used for repayment of the $125,000 due the trust company on a loan.

Johnson, it is alleged, may have used funds from the mortgaged property in Spokane to pay $35,000 operating expenses of a plant in Los Gatos, Calif., including payroll. He is also a partner in several business firms, the affidavit declares, including Ampitheatre, Northwest Motor-In, Aurora Motor-In and the Garland theater, Johnson & Spracher, E. W. Johnson Insurance company, Swanberg & Johnson and Olympic Distributors.

The affidavit asserts that a "purported accounting" has been made by Pacific Electronics, but that it is "contradictory."

The radio company sued Washington Trust last spring, asking $649,705 for alleged breach of contract in failure to pay a balance due on a $250,000 loan and for conversion of the electronics firm's stock and loss of business.

The News-Review (Roseburg, Oregon) · 09 Jun 1961, Fri · Page 11

Mr. and Mrs. W. F. Wilson, owners of Wilson's Studio in Roseburg, had interesting visitors as house-guests the last several days, when they entertained Captain and Mrs. Harold Kildall of Seattle. Captain Kildall, who is now retired, was written up in an article in the Reader's Digest, which told of the dog losing its ship and being taken by Captain Kildall, owner of the Kildall Navigation School in Seattle, aboard a ship to Singapore, where the dog again found his own ship and boarded it. This last year Captain and Mrs. Kildall enjoyed a tour of Europe and while in Denmark visited the author of the article printed about Captain Kildall and the lost dog appearing in the Reader's Digest. The Kildalls and Wilsons have been friends for many years.

1963 (March 25) - "Fairbanks Daily News Miner" :

Source pages : [HN01A2][GDrive] and [HN01A3][GDrive]

OFFICIALS HAD WARNED, BUT . . .

Experts Not Consulted, Ferry Docks Are Taking a Beating

SKIPPER — Here is Capt. Casey Moran, who spent part of his childhood in Fairbanks and is now skipper of the Malaspina. Speaking of terminals in relation to wind and tide, Moran wonders who advised state officials on the locations.

BY JEROME SHELDON
Special to the News-Miner

KETCHIKAN — "I wouldn't put another dime in those terminals!" exploded Capt. Casey Moran, one of the most experienced mariners in Southeastern Alaska waters.

His criticism, added to the mounting outcry emanating from the state capital, is aimed at the most basic operational flaw of the new Alaska Marine Highway System.

In the latest reported incident, the ferry Malaspina knocked out a "dolphin," the guard rail and 80 feet of piling of the dock structure at Petersburg.

Parts of the debris were carried to Ketchikan on the car deck. Scratches on the ship's high, blue sides were hastily covered with paint after she tied up at the Standard Oil Company dock here to refuel.

No injuries were reported, but the pride of the captain in his own seamanship undoubtedly was hurt in the unfortunate docking at a poorly located terminal.

"Don't blame the skipper," editorialized the Ketchikan Daily News, in commenting on the situation. "After all, the powers-that-be were warned far in advance that locations of the terminals . . . were not the proper ones in view of tidal conditions and type of construction called for."

Tricky Locations

At Ketchikan, also, the terminal has felt the brunt of the ship's "pile-buster" bow. The dock has been repaired. But with the next gusty wind when the ferry comes in, the damage probably will be repeated.

Skagway's dock, too, is in a tricky location for the skipper of any ship, situated as it is at the head of Lynn Canal crosswise to the prevailing winds and tidal currents.

A legislative inquiry is underway with regard to the location and construction of the state ferry terminals. The information sought by the legislators was available a year ago, before the first piling was ever driven, Captain Moran declared.

He, himself, sounded a warning to various lawmakers now concerned with the matter, he said.

Of the officials, engineers and consultants involved, he rather bluntly said, "None of them knew a damn thing about this country to warrant their putting in the ferries."

And he added, "I would like to know the thoroughly experienced Alaskan mariner who advised them."

Captain Moran, owner of Alaska's only resident ship piloting service, said he — for one — was never consulted with regard to the location of the ferry terminals.

His qualifications would seem to speak for themselves. He holds an unlimited master's license and a first class pilot's license for Puget Sound, Southeastern and Southwestern Alaska — both for ships of any gross tonnage. His business for the past 10 years has been to guide freighters or oil tankers through tortuous channels, with their shifting tides and ever-changing winds, to the pulp mills at Ketchikan and Sitka, to canneries and saw-mills, or to the Army's pipeline terminal at Lutak, near Haines.

He probably knows Alaskan waters as intimately as any sailing vessels of large tonnage to these parts. The pilot was graduated from the Puget Sound Nautical College in 1924 and from Capt. Harold Kildall's Nautical School in Seattle in 1928. Captain Kildall was noted in sea-

faring circles as a teacher.

During World War II, he was on the staff of Admiral Zeusler, commandant of the 17th Naval District. As assistant district marine engineer, Captain Moran handled a large ship salvaging operation at Ketchikan.

Though not Alaskan born, Captain Moran has a love for Alaska that's deeply-rooted in the gold rush era. His father, Casey Moran, went to Dawson in 1898 as a newspaperman. Later he worked on a newspaper in Fairbanks.

Young Casey was born in Seattle, but he spent the early years of his childhood in Fairbanks where his brother and sister were born.

The elder Moran took his family Outside in 1909, the year of the Alaska-Yukon Pacific Exposition. His career led from the Seattle Daily Times and Post-Intelligencer to Hearst's New York Journal. Eventually he went to South America and established English-language papers in Caracas and Maracaibo, Venezuela. He died in 1934.

"Pile-Buster" Bow

Ketchikan's ferry terminal juts into Tongass Narrows from the city's north end. The dock structure and transfer span are several hundred feet out in the water. The approach is provided over rock and gravel fill over the tidelands.

The dock structure is T-shaped. The top of the "T" is a row of pile bents on either side of the transfer span. The bents are cross-braced groups of piling supporting a walkway for those who receive the ship's lines when she ties up.

An outer row of piles facing the dock are in danger of being ripped out by the ship's "pile-buster" bow when the wind or currents slam the ship in too hard.

The ship is constructed with a projecting ledge running the length of the ship — at the water line — on either side. The angle at which it projects causes the "pile busting" effect, mariners say.

The transfer span is raised and lowered by a counter-balance system. It permits vehicles and passengers to board the ship through the large, side port, no matter what may be the stage of the tide.

Here, the dock structure cost $47,500. Bid prices on other terminals in Southeastern Alaska ranged from $59,314 (for Sitka) to $76,085 (for Haines and Skagway). These were all subject to negotiation for a smaller figure, for the state was short on cash.

Captain Moran said of the location chosen for the terminal ,the channel is subject to "very strong currents on the big, winter tides." The ships approach the dock broadside to the prevailing winds. He said this was "the most dangerous condition" for docking a vessel.

A Ketchikan construction man, who preferred that his name not be used, said the terminal could be changed in direction about 30 degrees for better wind and current conditions.

It would then face in the same direction as the nearby Nakat Packing Co. cannery. There would be a sizable cost for dredging and driving piling for a new dock.

Saxman Prefered

Captain Moran would prefer to place the ferry terminal at nearby Saxman where, he said, the wind is "fair with the current" and docking conditions would be easier.

Saxman is the site of the new Ketchikan & Northern Terminal Co. rail-barge terminal. It is "semi-public" in that an Area Redevelopment loan was obtained for part of its financing.

This was one of the sites considered last year for a ferry terminal. According to quoted statements of Public Works Commissioner Richard A. Downing at the time, the channel south of Ketchikan was rejected because of the expense of driving piling.

Captain Moran argued the freight-hauling capacity of the ferry system could be tripled if the ferries used the Saxman terminal. Merchandise could be transferred directly from the terminal warehouse to the ships without an expensive and time-consuming haul through town to the present ferry terminal on the north side.

With the railroad tracks planked over, the same transfer span could be used for the ferries as for the rail-barges from Prince Rupert. Stern loading could be employed, as at the Prince Rupert ferry terminal, Captain Moran said.

Commenting on other ferry terminal sites, he said those at Wrangell, Petersburg and Skagway are subject to conditions similar to those at Ketchikan.

He agreed with the feelings of ship officers who have stopped here that the terminal at Lutak (Haines) is the best. It is off one end of the Army's pipeline terminal dock.

The dock at Skagway should be re-located, Captain Moran said, to the end of the White Pass & Yukon Route wharf. This is situated at the side of the harbor, under the cliffs.

Favors Ferries

"I'm very much in favor of the ferries," Captain Moran emphasized. "The people in Fairbanks and Anchorage — the Interior—are the ones who will stand to gain the most.

"They will derive the biggest benefit because it will provide a second route North. The average person seeing the Panhandle on the map, will say, 'That's not even Alaska,' and will keep on driving."

But he argued the terminals should be re-located. It's easy, he explained, to pick a docking site, then say to a licensed shipmaster, "You take it in."

"Docking, or undocking, is the greatest hazard in navigation. Records show that more docks are knocked down than ships are lost while underway.

"It's very unjust to masters of vessels to build docks without getting not one man's, opinion, but that of a group of masters competent to go in with a ship."

Joseph Kildall - from 1916 book on Seattle history

Source : [HB004T][GDrive]

JOSEPH KILDALL

Joseph Kildall, president and manager of the Panama Pacific Commercial Company, was born in Norway, in March, 1865. His father, Michael Kildall, was a merchant and a large operator in the fish business in Horstad, Norway, for a number of years. He came to .America in 1888, crossing the Atlantic five years after the arrival of his son Joseph in the new world.

It was in 1883 that Joseph Kildall, then a youth of eighteen years, bade adieu to friends and native land and sailed for the new world, attracted by the favorable accounts which he heard concerning the business chances to be found in America. He made his way

to the Pacific coast, settling first in Tacoma, Washington, where he entered the employ of Hansan & Company, conducting a milling business at that place. Still later Mr. Kildall made his way to San Francisco, but remained in California for only a year. He afterward went to Port Gamble, Washington, and entered the employ of the **Puget Sound Mill Company**, with which he continued for three years, acting as a salesman in their store. He afterward embarked in general merchandising on his own account at Lynden, Washington, and there continued in business until 1892. He then turned his attention to steamboat interests, operating steamboats between Bellingham, Seattle and Tacoma, and still later he became connected with the fish industry on Puget Sound, making his headquarters at Bellingham. In 1897 he removed to Minneapolis, Minnesota, where he established the **Kildall Fish Company**, one of the largest wholesale fish houses of the United States, remaining in that city until 1911, supervising the interests of the company. In the meantime he organized the **Pacific Coast & Norway Packing Company**, with headquarters at Petersburg, Alaska. This company conducted a general merchandise, canning and saw-milling business, owned the town site and built up the town of Petersburg. Mr. Kildall also organized the **Kildall-Bright Company of Chicago, Illinois**, which did a very large importing business and engaged in the sale of foreign and domestic fish. In 1911. however, he decided to return to the Pacific coast and settled in Seattle. After investigating the Sound country, the geographic location, the climate and other conditions led to his choice. He became identified with several companies in the general fish business, packing, marketing and superintending several fish industries on the coast, operating throughout America and foreign countries in the shipment and marketing of fish. This business has been organized under the name of the **Panama Pacific Commercial Company**, a corporation which is capitalized for a large amount and which is now conducting an extensive business throughout the Pacific coast country, being one of the foremost concerns of the kind in the west.

In Bellingham, Washington. Mr. Kildall was united in marriage to **Miss Mary Jenkins**, a daughter of **Judge John R. Jenkins**, of that city, and one of its early settlers. **He served as justice of the peace at Bellingham for a number of years and for a long period was in the hotel business, but passed away about 1907**. Mr. and Mrs. Kildall have become the parents of two children, **Blanch and Harold**, aged respectively twenty-three and twenty-two years, the latter now assisting his father in the office work.

In politics Mr. Kildall has always been a stanch republican, working for the growth and success of the party, but at municipal elections where no political issue is involved he casts an independent ballot, considering only the capability of the candidate for office to which he aspires. He is a member of the **Transportation Club of Seattle** and he and his family attend the Trinity Episcopal church. Mr. Kildall has been a citizen of the new world for over thirty years and has been numbered among the representative business men of Seattle for five years. He has built up an immense business in his line, his well defined plans having been carried forward to successful completion. Energy and enterprise have enabled him to overcome obstacles and difficulties created by conditions and competition and he is today at the head of one of the foremost concerns of the kind on the Pacific coast. He has had broad experience and his powers have developed with the passing years, making him capable of controlling most important enterprises.

Bob Kildall

https://www.legacy.com/obituaries/seattletimes/obituary.aspx?n=robert-kildall-bob&pid=171476320

7/24/1920 ~ 6/16/2014

Our long farewell, as the Alzheimer's disease has been called, came to an end when Bob passed on June 16 at the age of 93.

Sadness was replaced by cheerful and happy memories of the man we knew and loved. The man who, although family always came first, set the tone for commitment to the community. He owned and operated Olympic Distributors, an office equipment business on Queen Anne, for 50 years, but his passion was Seattle's park system in particular and the urban environment in general. **He was chairman of the Board of Park Commissioners from 1975 to 1976**.

While he acquired the moniker Mr. Discovery Park for his passionate and tenacious fight for the integrity of Discovery Park as a wilderness sanctuary all through its existence, his biggest personal pride was Commodore Park at the Locks. In 1967, a group of Magnolia citizens together averted the development of apartment buildings. They got the property rezoned, and the result was the beautiful park we now have with promenades along the Canal.

One of Bob's great gifts in his dealings with officials as well as private parties of the numerous civic affairs he was involved in throughout his life was his wit and non confrontational style. He often managed to turn opponents into friends, some of them lifelong. His basic values of openness and acceptance of everybody on their own terms were disarming.

It was that same wit and lightheartedness that permeated our family life. Some of the jokes outlived themselves, but there were always new originals coming along.

[...]

A lifelong resident of Queen Anne and Magnolia, Bob is survived by wife Ruth of 49 years, daughters Katie Bucy (Tom), Maria Kildall, son Kristian Kildall and four grandchildren.

7/1/2017 History Article by Greg Dash : "Seattle Won a Park in a Battle With a Missile System Dr. Greg Dash"

Source : [HW0054][GDrive]

Discovery Park has approximately 644 acres of meadow, walks and trees on a high bluff overlooking Puget Sound and the Olympic Mountains. It is Seattle's largest and newest park, established on September 1, 1972.

But a few years earlier, it seemed destined to become a missile base, where radars and intercept missiles would be prepared to detect and destroy intercontinental ballistic missiles. The struggle to change that destiny took the dedicated efforts of citizens' organizations, political leaders and scientists.

On September 18, 1967 Defense Secretary Robert McNamara announced that the U.S. would build a light anti ballistic missile (ABM) system as a deterrent against expected Chinese missile attack in mid-1970's. The "Sentinel" ABM system would consist initially of ten radar and missile sites along the northern tier of states. It would be adequate to defend against a light attack by a small number of simple missiles, but it could not defend the country against a massive attack such as USSR could launch, An ABM defense against the USSR was impractical, and perhaps unnecessary in view of the effectiveness of the policy of Mutual Assured Destruction, whereby each country held the other's cities in hostage.

Skeptics thought that Sentinel might actually be the thin end of a wedge, a start for a much larger, eventually anti-Soviet system. Indeed, John Foster, Director of Defense Research and Engineering, testified that while politically the system was designed to protect against a Chinese attack, it would actually have some degree of effectiveness against Soviet missiles. And on the day after the announcement Senator Henry M. Jackson hailed the decision as a step toward a massive ABM system.

When more details of the ABM system were described, Fort Lawton in Seattle was mentioned as a possible choice for its westernmost base.

The fort was an army base originally intended for a coastal gun battery, but never activated. This came as a shock, for Seattle had been looking forward to acquiring all or a substantial part of Fort Lawton for a city park. Mayor Dorm Braman said that it was disappointing news, but if the system needed Fort Lawton to make Seattle safer, it would be worth the loss.

The idea of turning the base into a park had a long history. In 1910 the Olmsted Brothers, who designed many of the country's parks, included Fort Lawton in their plans for a Seattle park system. In 1917 an editorial in the Seattle Post Intelligencer called for the city to acquire the Fort, and the Mayor and city officials supported the paper's position.

In the mid 30's U.S. Representative Warren G. Magnuson proposed a bill to offer the entire site to Seattle for $1.00. However, what might have been a gift in normal times was then seen as a liability, for it was during the worst years of the Depression. The city declined the offer because it could not afford the cost of maintenance.

In 1964 the Secretary of Defense, announced that 85% of the site would be declared surplus. The citizens voted $3 Million in a Forward Thrust proposal to acquire the land for a public park. At the time of the Sentinel announcement it seemed that the conversion was close at hand. And so it came as a great disappointment, when a few years later the Army named Fort Lawton a prime candidate for one of the ten Sentinel bases.

Seattle's Mayor Braman, who had been trying to wrest Fort Lawton away from the Army, complained, "I am in no position and would not, under any circumstance, oppose the judgment of the qualified authorities if in fact ...Fort Lawton... is (needed to defend) the sector of the country.... On the other hand, if the mere fact that the property is currently owned by the government and that the amenities of the base in this location ...are the governing factors, I would strenuously object to the choice."

However, a Pentagon spokesman replied that "The missile hardware has to go in at Fort Lawton if it is to defend Seattle properly".

To a few scientists at the University of Washington, the case was not so obvious. Their opposition rested on two principles. The first was a conviction that missile defense was unwise. The second was that, if an ABM base were to be built in the Northwest, Fort Lawton would not be a necessary or desirable location.

The issue of missile defense had been debated within high level Defense Department advisory committees and in public for several years. The considered judgment of non- governmental defense experts was that there was no foreseeable technology for an effective antimissile system. Therefore, an ABM system built with currently available technology would be ineffective and wasteful. Furthermore it could actually increase the risk of war. At that time, we and the USSR opposed each other with thousands of intercontinental missiles. The sure knowledge that an exchange would destroy both countries led to a state of mutual deterrence.

But if one country could ward off an attack, or even if it prepared to defend against it, that would threaten the other's security. So if the Sentinel system were built, although it might be only a thin defense against a Chinese attack, it could give rise to Soviet fears that it would lead to a larger and more advanced anti Soviet ABM, and that would compromise the Soviet defense. In response to the threat, the Soviets were likely to increase the number of its missiles targeting the U.S., to be sure that an adequate number would get through.

Along with the national debate, these arguments were discussed in University of Washington seminars. Newell Mack, a Physiology graduate student, had been so concerned by signs that national policy seemed to be leading toward missile defense, that he had convinced members of a graduate seminar on Conflict Studies in the University of Washington to study the issue. He was joined in leading the discussions by Philip Ekstrom, a Physics graduate student.

The meetings had begun with one or two sessions on the technical aspects of missile defense, when the Sentinel ABM was announced, and Fort Lawton was mentioned as a possible choice for the key site for the West Coast. As a bonus, it was said to protect Seattle.

The seminar members were disappointed in the national decision, but they felt that perhaps not all was lost; Fort Lawton might be saved for a park if the Pentagon spokesman was wrong, and that Seattle's defense could be based somewhat outside of the city. To determine that, one would have to know the technical characteristics of the Sentinel system. Fortunately, the details had been published, in an issue of Aviation Week.

Each installation would have a large Perimeter Acquisition Radar, to detect an ICBM attack at long range, while the missiles were on their inertial trajectories well above the Earth's atmosphere. The PAR would alert the system to fire Spartan interceptor missiles, which would target the incoming

ICBMs while they were still in space. The Spartans, guided to their targets by the PAR, would be able to destroy them with their 1 megaton nuclear warheads even if they didn't make contact. The PAR radars would be protected by a "last ditch defense", a battery of short-range high acceleration Sprint missiles, which could intercept and destroy ICBMs penetrating the Spartan shield. In fact, it might be necessary to hold fire until the ICBMs entered the atmosphere, so that air resistance could discriminate between actual missiles and decoys. The Sprints carried 'small' nuclear warheads, about a kiloton.

Dr. Philip Ekstrom, with help from Physics Prof. Edward Stern, calculated the "footprint" of the protected zone. Ekstrom's calculation had as input data the speed and range of the Sprints, and the probable trajectories of the attacking ICBMs. The physics problem was a bit like finding the area that can be kept dry by an umbrella in a driving rain. The footprint turned out to be so large that the ABM base could be placed well outside of Seattle, and yet include the city in its protected area. His colleague, Physics Prof. Greg Dash, described the good news in a March 31 The Seattle Times story; Fort Lawton could be saved for a park, and Seattle could have both missiles and picnics. Dash pointed out that the PAR site for the Northwest would be the key detection unit for the entire West Coast. If it were placed at Fort Lawton, Seattle would become a prime target. An enemy intending to attack San Francisco or Los Angeles would have to take out Seattle's radar unit in order to assure that its missiles could get through. Furthermore, having 1 kiloton warheads explode at close range could be suicidal, with fallout from airbursts.

The news gave a great boost to the public campaign, which became known as The Battle of Fort Lawton. The campaign had remarkably wide support, with twenty-five citizen and professional organizations, such as the Seattle chapters of the American Institute of Architects, the Federation of American Scientists, the Magnolia Community Club, the League of Women Voters, and The Mountaineers. They were joined into one group, Citizens for Fort Lawton Park, headed by Donald Voorhees, a prominent Seattle lawyer, who was a leader in Seattle's improvement activities. Strong support came from Senators Henry Jackson and Warren Magnuson, and Congressmen Thomas Pelly and Brock Adams, Mayor Braman, other city officials and The Seattle Times editor Herb Robinson and reporter Svein Gilje. The campaign was carried out in letters to newspapers, editorials, radio interviews, and personal contacts between the senators and the Sentinel system's director Gen. Alfred Starbird, for over a year. Yet the Army Defense Command and Gen. Starbird continued to claim that Seattle's defense required the an-city location.

The public campaign now was intensified by the realization that an ABM at Fort Lawton would increase the city's vulnerability.

As the criticism increased, Defense Department officials tried to explain that the dangers were overdrawn, but their arguments were unconvincing. In an October interview John Foster scoffed at the scientists' concern at having nuclear weapons based in the city. Foster claimed that the explosion of a Spartan warhead outside the atmosphere would be hardly noticeable, and the atmosphere would filter its fallout over a long period. The Sprint's one-kiloton warhead would be too low to cause damage. The group found his claims incredible and his breezy dismissal infuriating.

Senator Jackson then asked the scientists' group for detailed data showing alternative sites that could satisfy Sentinel's strategic plan. Ekstrom and Stern supplied it in late August. A few days later Jackson met with Gen. Starbird, and extracted a promise that the general would meet with a representative of the scientists and listen to arguments for alternate sites. Stern flew to Washington in mid September and offered three alternate sites.

A week later a Pentagon source informed The Seattle Times' reporter, Svein Gilje, that the alternate sites would not be feasible. Besides, he added, why look for others when the Army already owns a perfect site, Fort Lawton?

Senator Jackson suggested that perhaps the Army had not done all its homework. Senator Magnuson complained that Fort Lawton "would be the worst possible site that anyone could imagine."

On Dec.12, 1968 a crucial meeting was held in the Mayor's Office on the fate of "Ft. Lawton: Anti-Ballistic Missile Site or City Park?" Attending were 16 representatives of civic and environmental groups, Donald Voorhees, chairman of Citizens for Ft. Lawton Park, Senator Jackson, General Starbird, and Mayor Braman. Robert Kildall represented the Magnolia Community Club, a district surrounding Ft. Lawton. He said, in part, "General Starbird, I represent those citizens who would be most affected by an ABM site at Ft. Lawton.... We are overwhelmingly opposed to the placement of ABMs here." "The will of our citizens- as represented by these sixteen civic and environmental organizations around this table- is that if Ft. Lawton is the only place we can defend those things that are dear to us, so be it! But if there are other sites, move it! A park represents one of those important values we have that are worth fighting for."

On the next morning, Sen. Jackson had breakfast with Defense Secretary Clark Clifford in the Secretary's office. Jackson had flown in minutes before from Seattle in a military plane. He was there to transmit the strong feelings that had been expressed in Mayor Braman's meeting. Clifford told him that he was aware of Seattle's desire to preserve the open space, but he had not yet heard from Gen. Starbird; he promised that he would ask for a report from the General over the weekend and have a decision a few days later. Starbird, in turn, was reported to have been convinced that Seattle's arguments for open space were valid, and official policies for retaining Ft. Lawton for missiles were contradicted with technical arguments showing the feasibility of alternate sites.

On Dec. 22nd, the day promised for the decision, Sen. Jackson telephoned Secretary Clifford, who told him the good news: the ABM would go to an alternate site.

But there was still one more hurdle before the Army could turn over the property; there was a question of price. Under current federal law, the city would have to pay $37.5 million, equal to one-half of fair market value, to receive the land. The problem was solved by an amendment to the Land and Water Conservation Act, which enabled state and local governments to acquire surplus property free or at less than 50 percent of fair market cost. The Senate's bill was sponsored by Senator Jackson, and the House bill was shepherded by Congressmen Adams and Pelly. Together, the legislation became known as the 'Fort Lawton bill'.

Epilogue

This account has focused on Seattle's campaign, but there were other local groups that waged campaigns against Sentinel. In Berkeley and the Bay Area, Minneapolis, Chicago, Detroit, New York, Pittsburgh and Boston, groups opposed the establishment of nearby sites, or fought against the system as a whole. The opponents were partially successful. In March 1969 President Nixon announced that Sentinel's city defense would be abandoned in favor a "Safeguard" system, a defense of Minuteman ICBM sites. The change, in an influential paper by Harold Agnew, the Leader of Los Alamos' Weapons Division, was advisable because "...defense installations are primarily located in areas of existing military bases thus minimizing problems presently being posed by citizens worried over safety matters or angered over dislocation problems." However, Safeguard failed to get strong political support and adequate financing, and in the end, only two sites were constructed.

In 1971 Anne Cahn earned her Political Science Ph.D. from M.I.T. with a study of the scientists' influence in the struggle. She concluded, in part, "Across the country scientists, mostly Outer (i.e. non Defense Department), younger, not scientifically prominent men took it upon themselves to alert, inform and

educate the public about ballistic missile defense."

"The important event, in our opinion, was that scientists took their case to the people."

Missile defense was proposed again by President Reagan on March 23, 1983. The initial design of the Strategic Defense Initiative (SDI) was to provide a nearly perfect "astrodome" defense. It would rely on space-based laser or electron beams to disable attacking ICBMs. The system would be powered by orbiting nuclear power reactors. Vigorous opposition came from scientists. Particularly cogent criticism came from a committee of the American Physical Society, in a paper analyzing beam weapons. In an effort to answer the criticism the design was changed to "kinetic energy weapons", which would rely on direct impact. A furious national debate over the technical feasibility and the political effects of SDI eventually led to its failure to get congressional support.

In 1996, the Secretary of Defense announced a new program, National Missile Defense. NMD was begun as a technology development effort leading to deployment of system that would protect all 50 states from a limited strategic missile attack by a rogue nation. The system would detect the launch of enemy missiles and track them by surveillance satellites and ground based radars, and then guide-defending ABM's to intercept the incoming missiles. In response to the opposition to the previous two ABM system designs, nuclear warheads and nuclear reactors in orbit would be replaced by ground based defending missiles, and they would be kinetic energy, "hit-to-kill" weapons. However, a succession of tests has shown the difficulty of achieving direct impacts. Many attempts to hit the incoming missile have largely failed, in spite of advance knowledge of the launch time and trajectory of an incoming missile, even when carrying a beacon. Nevertheless, the administration of Pres. George W. Bush has decided to begin preparing the first site. But the system is already aiming at its first target: the Antiballistic Missile Treaty. In 1972 the United States and the Soviet Union agreed to forego missile defense, in order to avoid threatening each other's deterrence forces. But defense policy makers are now preparing to discard that policy for an unproven NMD system. Although the current system is far from ready, in the words of a Defense Department official. "We do not have the luxury of waiting" until the system is proven to be effective."

In a crowning bit of irony, the chairman of the Defense Science Board, reported last year that the continual test failures with the 'hit-to-kill' method has caused the Bush administration to consider putting nuclear warheads on the interceptor missiles.

But meanwhile, Seattle can look back at its fight against an ABM system 38 years ago, (in 2006) and take pleasure in its victory, which won it a beautiful city park.

April 18, 2012 4:09 AM - "Bob and Ruth Kildall: A love sparked by the World's Fair"

By Mike Dillon ; Source : Queen Anne News (.com) : [HM000X][GDrive]

The Seattle World's Fair created all kinds of legacies that still resonate, starting with the Seattle Center campus.

For Bob and Ruth Kildall of Magnolia, memories of the fair take on a more personal meaning: It's where they met.

Ruth, who grew up in a small town near Copenhagen, arrived in Seattle in 1962 as a 28-year-old hostess for the Denmark Pavilion. Back home, Ruth had worked as a translator of business documents — moving between Danish, English, French and German. Boring stuff, she said.

She jumped at the chance to work at the World's Fair.

"It was exciting," Ruth recalled. "We didn't know what we were getting into."

Copenhagen was Ruth's measure of a big-time city; Seattle struck her as a little provincial. Still, there were cultural nuances she had to learn the hard way.

Ruth and two of her hostess friends rented a cramped space on Taylor Avenue for $90 per month — nothing to sneeze at in those days. Rent gouging was part of the World's Fair scene. The trio finally changed quarters.

There was more.

"Back in Denmark only people invited to parties showed up," she laughed. But not in America: "We were shocked."

American gregariousness had its upside: "We were struck by the hospitality of the American people," Ruth said. "There were people we could have visited in every single state."

The Denmark Pavilion showcased Danish wares: furniture, industrial design, jewelry and other goods.

"I was so impressed that little Denmark exported this to the country of IBM," she noted. "Little did we know IKEA would be taking over 50 years later."

Bob Kildall, owner of Olympic Distributors, Inc., carried a Danish-made electronic stencil cutter, which was cutting edge in its day. Bob was a regular in the Danish venue.

Their relationship remained Platonic as the fair wore on. Meanwhile, Ruth took in fellow Dane Victor Borge's piano-comedy show, but the classical music lover skipped a chance to see Elvis. She's still kicking herself.

The Fair ended on a warm Sunday, October 21, 1962. "We went wild in the fountain outside the Pavilion," Ruth said.

And she headed back home.

There are different versions of what happened next, but this version, which reflects Bob's dry sense of humor, is a good bet.

Workers in the Denmark Pavilion, including Bob, had been given fine, Danish tea sets. Not long after the fair ended, he called Ruth in Denmark.

"Why don't we put our tea sets together so we can entertain more people?" he asked.

And they did.

Dorothy McEwen Kildall

Karen Kildall

Children

Scott and Kristen[3]

Gary Arlen Kildall (/ˈ kɪldˌɔːl/; May 19, 1942 – July 11, 1994) was an American computer scientist and microcomputer entrepreneur who created the CP/M operating system and founded Digital Research, Inc. (DRI). Kildall was one of the first people to see microprocessors as fully capable computers, rather than equipment controllers, and to organize a company around this concept.[4] He also co-hosted the PBS TV show *Computer Chronicles*. Although his career in computing spanned more than two decades, he is mainly remembered in connection with his development of the CP/M operating system, an early multi-platform microcomputer OS that has many parallels to the later MS-DOS used on the IBM PC.

Early life

Gary Kildall was born and grew up in Seattle, Washington, where his family operated a seamanship school. His father, Joseph Kildall, was a captain of Norwegian heritage. His mother Emma was of half Swedish descent, as Gary's grandmother was born in Långbäck, Sweden, in Skellefteå Municipality, but emigrated to Canada at 23 years of age.[5]

Gary attended the University of Washington (UW) hoping to become a mathematics teacher, but became increasingly interested in computer technology. After receiving his degree,[1] **he fulfilled a draft obligation to the United States Navy by teaching at the Naval Postgraduate School (NPS) in Monterey, California**.[6] Being within an hour's drive of Silicon Valley, Kildall heard about the first commercially available microprocessor, the Intel 4004. He bought one of the processors and began writing experimental programs for it. To learn more about the processors, he worked at Intel as a consultant on his days off.

Kildall briefly returned to UW and finished his doctorate in computer science in 1972,[2] then resumed teaching at NPS. He published a paper that introduced the theory of data-flow analysis used today in optimizing compilers[7] (sometimes known as Kildall's method), and he continued to experiment with microcomputers and the emerging technology of floppy disks. Intel lent him systems using the 8008 and 8080 processors, and in 1973, he developed the first high-level programming language for microprocessors, called PL/M.[6] For Intel he also wrote an 8080 instruction set simulator named INTERP/80. He created CP/M the same year to enable the 8080 to control a floppy drive, combining for the first time all the essential components of a computer at the microcomputer scale. He demonstrated CP/M to Intel, but Intel had little interest and chose to market PL/M instead.[6]

Business career

CP/M

Kildall and his wife Dorothy established a company, originally called "Intergalactic Digital Research" (later renamed as Digital Research, Inc.), to market CP/M through advertisements in hobbyist magazines. Digital Research licensed CP/M for the IMSAI 8080, a popular clone of the Altair 8800. As more manufacturers licensed CP/M, it became a de facto standard and had to support an increasing number of hardware variations. In response, Kildall pioneered the concept of a BIOS, a set of simple programs stored in the computer hardware (ROM or EPROM chip) that enabled CP/M to run on different systems without modification.[6]

CP/M's quick success took Kildall by surprise, and he was slow to update it for high density floppy disks and hard disk drives.[*citation needed*] After hardware manufacturers talked about creating a rival operating system, Kildall started a rush project to develop CP/M 2.[8] By 1981, at the peak of its popularity, CP/M ran on 3000 different computer models and DRI had US$5.4 million in yearly revenues.[6]

IBM dealings

IBM, presided by John R. Opel, approached Digital Research in 1980, at Bill Gates' suggestion,[9] to negotiate the purchase of a forthcoming version of CP/M called CP/M-86 for the IBM PC. Gary had left negotiations to his wife, Dorothy, as he usually did, while he and colleague and developer of MP/M operating system Tom Rolander used Gary's private airplane to deliver software to manufacturer Bill Godbout.[4][10] Before the IBM representatives would explain the purpose of their visit, they insisted that Dorothy sign a non-disclosure agreement. On the advice of DRI attorney Gerry Davis, Dorothy refused to sign the agreement without Gary's approval. Gary returned in the afternoon and tried to move the discussion with IBM forward, but accounts disagree on whether he signed the non-disclosure agreement, as well as if he ever met with the IBM representatives.[11]

Various reasons have been given for the two companies failing to reach an agreement. DRI, which had only a few products, might have been unwilling to sell its main product to IBM for a one-time payment rather than its usual royalty-based plan.[12] Dorothy might have believed that the company could not deliver CP/M-86 on IBM's proposed schedule, as the company was busy developing an implementation of the PL/I programming language for Data General.[13] Also possible, the IBM representatives might have been annoyed that DRI had spent hours on what they considered a routine formality.[10] According to Kildall, the IBM representatives took the same flight to Florida that night that he and Dorothy took for their vacation, and they negotiated further on the flight, reaching a handshake agreement. IBM lead negotiator Jack Sams insisted that he never met Gary, and one IBM colleague has confirmed that Sams said so at the time. He accepted that someone else in his group might have been on the same flight, but noted that he flew back to Seattle to talk with Microsoft again.[10]

Sams related the story to Gates, who had already agreed to provide a BASIC interpreter and several other programs for the PC. Gates' impression of the story was that Gary capriciously "went flying", as he would later tell reporters.[14] Sams left Gates with the task of finding a usable operating system, and a few weeks later he proposed using the operating system 86-DOS—an independently developed operating system that implemented Kildall's CP/M API—from Seattle Computer Products (SCP). Paul Allen negotiated a licensing deal with SCP. Allen had 86-DOS adapted for IBM's hardware, and IBM shipped it as IBM PC DOS.[11]

Kildall obtained a copy of PC DOS, examined it, and concluded that it infringed on CP/M. When he asked Gerry Davis what legal options were available, Davis told him that intellectual property law for software was not clear enough to sue.[15] Instead Kildall only threatened IBM with legal action, and IBM responded with a proposal to offer CP/M-86 as an option for the PC in return for a release of liability.[16] Kildall accepted, believing that IBM's new system (like its previous personal computers) would not be a significant commercial success.[17] When the IBM PC was introduced, IBM sold its operating system as an unbundled option. One of the operating system options was PC DOS, priced at US$40. PC DOS was seen as a practically necessary option; most software

titles required it and without it the IBM PC was limited to its built-in Cassette BASIC. CP/M-86 shipped a few months later six times more expensive at US$240, but sold poorly against DOS and enjoyed far less software support.[4]

Later work

With the loss of the IBM deal, Gary and Dorothy found themselves under pressure to bring in more experienced management, and Gary's influence over the company waned. He worked in various experimental and research projects, such as a version of CP/M with multitasking (MP/M) and an implementation of the Logo programming language.[6] He hoped that Logo, an educational dialect of LISP, would supplant BASIC in education, but it did not.[18] After seeing a demonstration of the Apple Lisa, Kildall oversaw the creation of DRI's own graphical user interface, called GEM. Novell acquired DRI in 1991 in a deal that netted millions for Kildall.[15]

Kildall resigned as CEO of Digital Research on 28 June 1985, but remained chairman of the board.[19]

Kildall also pursued computing-related projects outside DRI. During the seven years from 1983 to 1990 he co-hosted a public television program on the side, called *Computer Chronicles*, that followed trends in personal computing.

In 1984 he started another company, *Activenture*, which adapted optical disc technology for computer use.[20] In early 1985 it was renamed *KnowledgeSet* and released the first computer encyclopedia in June 1985, a CD-ROM version of Grolier's *Academic American Encyclopedia*[11][20][13] named *The Electronic Encyclopedia*,[21] later acquired by Banta Corporation.[22] Kildall's final business venture, known as *Prometheus Light and Sound* (PLS) and based in Austin, Texas, developed a home PBX system[6] that integrated land-line telephones with mobile phones.

Personal life

Kildall's colleagues recall him as creative, easygoing, and adventurous. In addition to flying, he loved sports cars, auto racing, and boating, and he had a lifelong love of the sea.[4][6]

Although Kildall preferred to leave the IBM affair in the past and to be known for his work before and afterward, he continually faced comparisons between himself and Bill Gates, as well as fading memories of his contributions. A legend grew around the fateful IBM-DRI meeting, encouraged by Gates and various journalists,[*citation needed*] suggesting that Kildall had irresponsibly taken the day off for a recreational flight, and he became tired of constantly having to refute that story.[13] In later years, he had occasional private expressions of bitterness at being overshadowed by Microsoft.[6]

Kildall was annoyed when the University of Washington asked him, as a distinguished graduate, to attend their computer science program anniversary in 1992, but gave the keynote speech to Gates, a dropout from Harvard. In response, he started writing his memoir, *Computer Connections*.[15] The memoir,[23][24][25] which he distributed only to a few friends, expressed his frustration that people did not seem to value elegance in software,[18] and it said of Gates, "He is divisive. He is manipulative. He is a user. He has taken much from me and the industry." In an appendix he called DOS "plain and simple theft" because its first 26 system calls worked the same as CP/M's.[26] He accused IBM of contriving the price difference between PC DOS and CP/M-86 in order to marginalize CP/M. The journalist Harold Evans used the memoir as a source for a chapter about Kildall in the 2004 book *They Made America*, concluding that Microsoft had robbed Kildall of his inventions.[13] IBM veterans from the PC project disputed the book's description of events, and Microsoft described it as "one-sided and inaccurate".[15] In August 2016, Kildall's family made the first part of his memoir available to the public.[24][23][25]

Selling DRI to Novell had made Kildall a wealthy man, and he moved to the West Lake Hills suburb of Austin. His Austin house was a lakeside property, with stalls for several sports cars, and a video studio in the basement. Kildall owned and flew his own Learjet and had at least one boat on the lake. While in Austin he also participated in volunteer efforts to assist children with HIV/AIDS. He owned a mansion with a panoramic ocean view in Pebble Beach, California, near the headquarters of DRI.

Death

On July 8, 1994, Kildall fell at a Monterey, California, biker bar and hit his head.[27] The exact circumstances of the injury remain unclear. He had been an alcoholic in his later years.[15][28] Various sources have claimed he fell from a chair, fell down steps, or was assaulted, because he had walked into the Franklin Street Bar & Grill wearing Harley-Davidson leathers.[12] He checked in and out of the hospital twice, and died three days later at the Community Hospital of the Monterey Peninsula. An autopsy the next day did not conclusively determine a cause of death.[26][3] A CP/M Usenet FAQ says he was concussed from the fall and died of a heart attack; the connection between the two are unclear.[29] He is buried in Evergreen Washelli Memorial Park in north Seattle.

Recognition

Following the announcement of Kildall's death, Bill Gates commented that he was "one of the original pioneers of the PC revolution" and "a very creative computer scientist who did excellent work. Although we were competitors, I always had tremendous respect for his contributions to the PC industry. His untimely death was very unfortunate and his work will be missed."[4]

In March 1995, Kildall was posthumously honored by the Software Publishers Association (SPA) for his contributions to the microcomputer industry:[30][31][6]

- The first programming language and first compiler specifically for microprocessors: PL/M. (1973)
- The first microprocessor disk operating system, which eventually sold a quarter of a million copies: CP/M. (1974)
- The first successful open system architecture by segregating system-specific hardware interfaces in a set of BIOS routines.[32][33][34][35] (1975)
- Creation of the first diskette track buffering schemes, read-ahead algorithms, file directory caches, and RAM drive emulators.
- Introduction of operating systems with preemptive multitasking and windowing capabilities and menu-driven user interfaces (with Digital Research): MP/M, Concurrent CP/M, Concurrent DOS, DOS Plus, GEM.
- Introduction of a binary recompiler: XLT86. (1981)[36]
- The first computer interface for video disks to allow automatic nonlinear playback, presaging today's interactive multimedia. (1984, with Activenture)
- The file system and data structures for the first consumer CD-ROM. (1985, with KnowledgeSet)

Archived from the original on 2016-11-24. Retrieved 2013-06-03. [...] The first commercial licensing of CP/M took place in 1975 with contracts between Digital Systems and Omron of America for use in their intelligent terminal, and with Lawrence Livermore Laboratories where CP/M was used to monitor programs in the Octopus network. Little attention was paid to CP/M for about a year. In my spare time, I worked to improve overall facilities [...] By this time, CP/M had been adapted for four different controllers. [...] In 1976, Glenn Ewingapproached me with a problem: Imsai, Incorporated, for whom Glenn consulted, had shipped a large number of disk subsystems with a promise that an operating system would follow. I was somewhat reluctant to adapt CP/M to yet another controller, and thus the notion of a separated Basic I/O System (BIOS) evolved. In principle, the hardware dependent portions of CP/M were concentrated in the BIOS, thus allowing Glenn, or anyone else, to adapt CP/M to the Imsai equipment. Imsai was subsequently licensed to distribute CP/M version 1.3, which eventually evolved into an operating system called IMDOS. [...]

Killian: "[...] Intel had hired him a few months earlier to write a control program monitor to run on their little demo system for 8008 and now 8080. [...] Glenn knew this and he would be talking with Gary, and he started twisting Gary's arm. He said, "Hey Gary, why can't we run this in this IMSAI?" "The I/O's all different, won't run." But Glenn persists and finally makes a deal with Gary. He says, "Okay Gary, if you split out the I/O, I'll write the BIOS, basic I/O's system," and Glenn named it then. "We'll split it out separately. I'll write that part, as long as you can make a division in the program there." And he got Gary to do that and Glenn put those two pieces together and was running Gary's CP/M on an IMSAI. Glenn let us know that, and it wasn't too much later than Billwas down there making arrangements with Gary Kildall to license CP/M. [...] Now that the BIOS is separated out, anybody could write a BIOS for their machine, if it was 8080-based, and run this, so he started selling that separately under the company Digital Research that he formed and did quite well."

RESUME OF GARY ARLEN KILDALL

Gary A. Kildall was born in Seattle, Washington, on 19 May 1942. He attended the University of Washington in Seattle where he majored in mathematics. He received the degree of Bachelor of Science in June 1967.

He attended Officer Candidate School in Newport, Rhode Island, and was commissioned in August 1967. He received a delay in reporting for active duty to pursue graduate study.

Remaining at the University of Washington, he did research in areas of computer science, including artificial intelligence, information retrieval, compiler design, and operating systems design. He received the degree of Master of Science in Computer Science in December 1968.

In January 1969 he reported for active duty at the Naval Postgraduate School, Monterey, California, where he taught in the Department of Mathematics.

Upon release from active duty in January 1972 he returned to the University of Washington where he received the degree of Doctor of Philosophy in June 1972. His research in the area of compiler code optimization was under the direction of Professor Hellmut Golde.

In March 1972 he joined the faculty of the Mathematics Department of the Naval Postgraduate School, Monterey, California. He is presently teaching in the Computer Science Group. His current research is in micro-computer organization and applications.

He is a member of the Association for Computing Machinery.

Gary Kildall, a pioneering computer scientist who created the first popular operating system for personal computers, died on Monday at the Community Hospital of the Monterey Peninsula in Monterey, Calif. He was 52.

An autopsy performed yesterday failed to determine the cause of death, said John DiCarlo, Monterey County's deputy coroner.

While teaching computer science at the United States Naval Postgraduate School in Monterey in 1973, Mr. Kildall wrote a personal computer operating system, a fundamental program that controlled the way the central processing unit stored and retrieved information from a floppy disk drive. He named the program Control Program/Monitor, or CP/M.

Before his program was available, inexpensive hobbyist microcomputers were generally programmed with a punched paper tape reader or by laboriously entering information by setting combinations of on-off switches to encode each byte. Founding Digital Research

With his wife, Dorothy McEwen, Mr. Kildall founded a company to sell the CP/M operating system from their home in 1974. At first they called the company Intergalactic Digital Research, but the name was quickly shortened to Digital Research.

In 1977 Digital Research licensed CP/M to IMSAI, one of the early makers of personal computers. In the years afterward the program became the standard operating system for the first generation of 8-bit microcomputers.

Even before the invention of the electronic spreadsheet, these machines quickly became useful for business applications like word processing and relational databases, and by the early 1980's Digital Research's yearly revenues were $5 million.

Despite his business success, Mr. Kildall stayed on for several years as a professor at the Naval Postgraduate School because he enjoyed teaching. Meeting With I.B.M.

In one of the most controversial events in the history of personal computing, Mr. Kildall was approached by I.B.M. in 1980 to develop a 16-bit version of CP/M for its new personal computer.

There is a legend in the computer industry that Mr. Kildall ignored the I.B.M. representatives who had arrived for a meeting and went flying in his airplane instead. But Mr. Kildall has said that in fact he attended the meeting and left believing that he had struck a deal with I.B.M.

In any case, I.B.M. executives later met with a small software company, the Microsoft Corporation, then located in Bellevue, Wash., founded by William Gates to sell his version of the BASIC computer language. Upon learning that I.B.M. was designing a personal computer, Mr. Gates, who at the time did not sell an operating system, rushed to buy one from a small Seattle company.

Eventually I.B.M. offered both Digital Research's CP/M-16 and Microsoft's MS-DOS operating systems with the I.B.M. PC. But it priced its version of the Microsoft operating system, PC-DOS, at $40 and the Digital Resarch operating system at $240.

PC-DOS quickly became the standard operating system for the I.B.M. PC, and when Compaq produced the first I.B.M.-compatible personal computer, MS-DOS became the industry standard. Microsoft eventually became the leading supplier of all kinds of personal computer software, and eventually broke with I.B.M. in a dispute over MS-DOS's successor operating system, OS2.

Many people in the computer industry argued that Microsoft's MS-DOS infringed on CP/M patents, but Mr. Kildall decided not to sue.

"In those days everyone was imitating everyone else," he said in a magazine interview several years ago. "That's why I didn't do anything about CP/M; it never occurred to me."

Mr. Kildall was widely viewed as a creative innovator in software design who disliked the cut-throat aspects of business and avoided many of the more aggressive tactics employed by his competitors in the computer industry.

Thomas Rolander, who was director of engineering for Digital Research when the company was approached by I.B.M., said he had flown with Mr. Kildall on the day of the I.B.M. meeting. He said he and Mr. Kildall arrived late at the meeting and refused to sign a nondisclosure document from the computer maker after the I.B.M. executives refused to sign a similar document presented by Digital Research.

Mr. Rolander said that several months later I.B.M. returned with an offer that included a royalty, but that I.B.M. had made the decision to price the two competing programs differently.

Mr. Kildall remained involved as chairman of Digital Research until the company was sold to Novell in 1991. He founded a second company in 1985 called Knowledge-Set to develop one of the first consumer applications for CD-ROM, a disc-based version of the Grolier Encyclopedia.

More recently, he moved to Austin, Tex., to found Prometheus Light and Sound, which is developing a "home PBX system."

Several years ago, he moved back to the Monterey area, where he began working on a book titled Computer Connections, a history of the computer industry. Mr. Kildall self-published the book earlier this year.

Mr. Kildall was born in Seattle and received his Ph.D. in computer science from the University of Washington. He and Ms. McEwen were married in 1962 and divorced in 1983. He is also survived by two children, Scott, of San Francisco , and Kristin, of Seattle, and by his mother, Emma, and sister, Patricia Guberlet, both of Seattle.

1986 (January) article in "Picos Journal" IBM Picks the Winner by Kevin Strehlo

IBM Picks the Winner

by Kevin Strehlo

Although a million CP/M computers have been sold, several million more run MS-DOS. How did the business of computing arrive at a standard?

It was a nice piece of business for Seattle Computer. Their project to write an operating system for the 8086 processor was under way anyway—they needed it for their own hardware. So getting some upfront money to finish the software, plus $10,000 for each customer Microsoft licensed it to, seemed like a great deal to Seattle Computer president Rob Brock.

Brock had his first glimmer of doubt about the wisdom of the deal one day late in 1980 when someone called Seattle Computer with a question.

"I'm with IBM," the voice said. "I want to know something about the operating system you're doing for us."

"You're with WHO?" Brock asked, his voice rising incredulously. The man on the other end of the receiver said "oops" and hung up.

When Brock mentioned the call to his employee Tim Paterson, who was writing the software to the specifications of Microsoft's customer, the two laughed about it and wondered if that customer might really be Big Blue. It seemed odd and, even if the customer was IBM, not necessarily significant. The chance that IBM would be able to make much of a dent in the wide open world of microcomputers—far from the tightly controlled, large sale environment of IBM—seemed pretty small. No one company dominated the personal computer business, and it seemed unlikely that IBM would be more than just another player in a crowded field.

Who's the Boss?

The one thing that did dominate personal computing was the CP/M operating system. Nearly every microcomputer used it—even the Apple II, although it required an add-on board with a processor that ran the 8080 instruction set. It seemed unreasonable that even IBM would switch from an industry standard as strong as CP/M.

It was only when Paterson went to work for Microsoft a few months later that he learned it was IBM. But even at the introduction of the IBM PC in August 1981, it wasn't clear that the MS-DOS operating system Tim Paterson had written, dubbed PC-DOS by the press—although IBM called it simply DOS—would be important.

IBM introduced the PC with three operating systems—PC-DOS, the p-system and CP/M 86. Even the market research firm, Future Computing, wrote that the most significant aspect of the new machine was that the PC ran CP/M.

But CP/M was not to dominate the personal computing world any longer, and Future Computing quickly changed its tune. Later reports by the Texas-based market research firm rated a new computer largely on a single factor: whether it could run off-the-shelf PC-DOS applications.

Today, while laptop computers remain a stronghold for CP/M, the majority of the action in software development and microcomputer sales has been with MS/PC-DOS machines.

How did it happen? Why did CP/M lose out to MS-DOS? Why is CP/M still important in the world of picocomputers? And what's the difference anyway? Is MS-DOS any better than CP/M?

The best way to answer these questions is to go back to the beginning.

The Birth of CP/M

In 1972, while Gary Kildall was teaching computer science at the U.S. Naval Postgraduate School in Monterey, Calif., he became intrigued with one of the first of a new type of semiconductor part called a microprocessor. Although the four-bit Intel 4004 was too limited to do anything useful, Kildall's curiosity was piqued by the idea of a computer on a chip, and he decided to visit the Silicon Valley company that was making the things and see what else Intel had cooking.

Kildall and the small group of engineers working on microprocessors at Intel hit it off, and soon Kildall found himself commuting inland from his ocean-side home one day a week to work at Intel. Using a minicomputer to simulate Intel's new eight-bit microprocessor, the 8008, Kildall soon had created a version of the PL-1 language that ran on it.

Kildall took one of the systems Intel sold as an aid in developing software for the new microprocessors as partial payment for his work. Although his students at the Institute loved to play with the 8008-based microcomputer (which was soon upgraded with the more powerful 8080 and a high-speed tape reader), Kildall knew it needed real data storage if it was going to be truly useful. He did some work for Shugart Associates in 1972 in exchange for one of the early eight-inch floppy disk drives. But Kildall, no hardware expert, failed in designing a controller board to interface the drive with his computer.

It was not until 1973, with John Torode from the University of Washington designing the hardware, that Kildall was able to write a simple operating system to control the transfer of data between the computer and the disk drive.

Despite the acronym DOS, which stands for Disk Operating System, there is more to such software than the kernel that Kildall had written to control the disk drive. However, Kildall wasn't focusing his attention on fleshing out his operating system kernel. The project he had great hopes for was a microprocessor-based horoscope machine that he and a friend built and installed in stores all around San Francisco. Although the work didn't pay off in the anticipated deluge of quarters—the mechanical part of the machine tended to jam after it had printed just a few horoscopes—it rounded out Kildall's kernel.

When he tacked the software development tools (an editor, assembler and debugger that aided the production of language the microprocessor understood) he had used to develop the horoscope program on to his kernel, Kildall had all the tools needed to write and run useful programs.

When Kildall showed his Control Program/Monitor (CP/M for short) to the powers that were at Intel, they said it had no commercial potential. The company thought its microprocessors would end up largely in watches, calculators and appliances, not in the kind of general-purpose microcomputers hobbyists were building.

<footer>8 PICO'S JOURNAL JANUARY 1986</footer>

[HT00BX][GDrive]

commercial potential. The company thought its microprocessors would end up largely in watches, calculators and appliances, not in the kind of general-purpose microcomputers hobbyists were building.

so CP/M and the Z80 microprocessor on which it ran became a kind of standard by default.

Not all computer manufacturers offered CP/M. Radio Shack substituted its proprietary TRS-DOS for the Z80-based TRS-80 computers, for example. But many TRS-80 users bought a version of CP/M tailored for the Radio Shack machines by other companies, such as Pickles and Trout, in order to run all the CP/M software.

The most popular personal computer in 1980 was unquestionably the Apple II, which couldn't run CP/M because it was based on the 6502 instead of the 8080 or Z80. Although much credit for the success of Apple's machine has to be given to the first spreadsheet, VisiCalc (which at first ran only on the Apple II under Apple's proprietary DOS), many Apple II owners bought an add-on card for their machines that included a Z-80 processor, memory and the CP/M operating system. This allowed them to run the ever-increasing pool of business software being written for DRI's operating system, including WordStar and dBASE II.

The most popular of such cards was the SoftCard, developed and sold by Microsoft. In fact, sales of the Softcard were so high that Microsoft became DRI's largest customer for CP/M. As 1980 rolled to an end, that fact was soon to take on an ironic twist.

CP/M Upgraded

When IBM decided to enter the microcomputer business, it went to Microsoft—on one-day's notice—for advice on what kind of machine to build and for several key pieces of software. Gates had to cancel an appointment with Atari's chairman Ray Kassar in order to meet with IBM, but he did it on the theory that if IBM was entering the microcomputer business as rumored, Microsoft should do anything it could to be a part of it—because IBM succeeded at nearly everything it tried.

Microsoft's BASIC interpreter had been an integral part of nearly every personal computer sold, and Microsoft's other languages were popular among software developers. Microsoft president Bill Gates knew microcomputers and the personal computer market as well as anyone. Thus it was no surprise when IBM asked Microsoft to make a proposal about developing languages for its planned machine and detail what the features of that machine should be.

No, it was no surprise that the computing industry veterans listened to president Bill Gates extol the new generation of 16-bit chips and the need for a disk drive—they were thinking of an 8-bit machine with a cassette interface. But it was a bit of a surprise when an IBM official responded by asking Gates to sell IBM CP/M as well. Gates patiently explained that CP/M belonged to a company 1,000 miles down the coast, DRI, headed by Gary Kildall. Gates dialed DRI's number and handed the phone to an IBM representative, who made an appointment for the next day.

Legend has it that Kildall was out on a joyride in his plane when IBM came calling. Actually, Kildall already had an appointment with a customer in Silicon Valley the next day and, unlike Gates, decided to keep it. After all, Dorothy McEwan always handled the business end of things with the firm's legal counsel anyway—why should a meeting with IBM be any different?

After concluding his business, Kildall flew back in the late afternoon and joined the meeting in progress, but things weren't going well. McEwan and DRI's legal counsel Jerry Davis had balked at the nondisclosure agreement IBM had asked them to sign, because it contained a clause that specified any information revealed in the meeting would become IBM's to use as it pleased. Since the meeting was about CP/M, McEwan thought such an agreement amounted to giving away the store, and refused to sign. The IBM representatives were on the verge of leaving when Kildall arrived.

Kildall, familiar with IBM's way of doing things, knew IBM was an honorable company. The nondisclosure document was meant to protect IBM from lawsuits in the event it later marketed similar technology

Gary Kildall, operating system pioneer, took his Control Program/Monitor and formed Digital Research, Inc.

<footer>PICO'S JOURNAL JANUARY 1986 9</footer>

[HT00BY][GDrive]

that had been developed independently within IBM. With Kildall's reassurances, the nondisclosure agreement was signed, the meeting proceeded and, according to Kildall, went rather well.

Gary and Dorothy, as it happened, were about to leave on vacation and had seats on the flight that took the IBM representatives back to Boca Raton, Fla. Discussion continued amiably during the flight, according to Gary, and they agreed to get back together after the Kildalls returned.

It never happened. Bill Gates has said the problem was Kildall's expression of reluctance to modify CP/M for IBM's requirements; Kildall believed a standard was a standard. In any case, IBM eventually came back to Microsoft and asked if the Bellevue, Wash., firm could do an operating system, as well as the languages. It added only another 10 percent or so to the amount of code Microsoft was to write for the new machine; more important, Microsoft knew the operating system under development at Seattle Computer nearly fit the bill. When Microsoft had described that operating system in writing and IBM agreed it would be fine, provided a few changes were made, Microsoft negotiated rights to Seattle Computer's 8086 DOS.

What Microsoft had really contracted for was the work of a person it knew quite well. Seattle Computer's Tim Paterson had taken the first couple of cracks at designing Microsoft's Z80 Softcard card for the Apple before another engineer finished up. Microsoft was also familiar with Paterson's latest product, a processor board for scientific and engineering computers based on the new 16-bit 8086 chip from Intel. Microsoft had used the board while writing its new BASIC for the 8086 and its compatible cousin, the 8088. The board was one of the first implementations of Intel's new chip. It was done so early that the documentation from which Paterson began designing in June was dated July, and talked about five and eight MHz chips when only four MHz chips were available.

The operating system Paterson was writing for his newboard was to be CP/M compatible so that CP/M programs for the eight-bit Z80 could simply be translated and run unchanged on the new 16-bit 8086. Paterson had no access to CP/M other than its documentation, however, and used as his chief model the CP/M look-alike operating system called CDOS that ran on the Cromemco machine they used at Seattle Computing.

Thus it was that some of the improvements of Paterson's DOS over CP/M were accidental. If CP/M encountered an open door when it was trying to read from a disk, for example, it would crash. Paterson's operating system, like the CP/M look-alike he used as a model, responded to an open door with an "Abort, retry or ignore?" message.

Some improvements were Paterson's idea, however. You could halt a program that was running under CP/M (and CDOS) only by rebooting the machine. Paterson decided the ability to "break" the operation of a program and return to the operating system prompt made more sense. He also thought that the need for the PIP utility program to be on the disk when you wanted to copy a file made no sense; nor did the terms PIP and "=" to describe the action of copying a file. Thus he decided to embed a file copying command with more sensible syntax right into his operating system. And whereas CP/M could destroy files if a user switched disks without telling CP/M such a switch had been made, Paterson made MS-DOS look at the disk in the drive before it wrote to it to prevent such disasters.

Perhaps the key thing Paterson tried to do was to speed up read and write operations. Borrowing from the compiled BASIC, he had helped Microsoft put on his 8086 board, he made his operating system keep information about files—called FATs (File Attribute Tables)—in memory instead of on the disk, which speeded file operations considerably.

It turned out that Paterson's DOS was not perfectly compatible with CP/M, however, because—at least according to Paterson—some of the features he copied from CP/M's documentation did not work exactly as documented.

The key difference between the operating systems, however, was due to differences between the chips for which they were written. The Z80 processor that CP/M was designed for could address only 64K bytes of memory, while the 8088 and 8086 processors Paterson wrote his DOS for could address one Megabyte (1,000K bytes) of memory. IBM, through Microsoft, told Paterson to use only 640K bytes of that memory and reserve the remaining 360K bytes for the system's use. Even so, it was hard to imagine that programmers would ever need more than a 10-fold increase in memory. It augered much-improved programs for the next generation of personal computers.

This key improvement of Paterson's DOS over CP/M was also a feature of Digital Research's CP/M-86, of course, since it also ran on the more advanced chips. So why did MS-DOS win?

IBM Picks the Winner

CP/M-86 was only a glan on a blackboard on that fateful day in 1980 when IBM called on DRI. Unfortunately, IBM never called back, and Kildall was unaware of the project's process until, shortly before the IBM PC was to be introduced in August of 1981, IBM returned and asked him to write an operating system for its new machine. Since demand for the Z80-based CP/M had not abated, not much work had been done yet on CP/M for the 8086; a team immediately got to work.

In retrospect, it is clear IBM wanted CP/M only as a backup in case its new operating system did not gain support among third party developers. IBM had clearly stacked the cards in its DOS's favor. The price of PC-DOS was $40 compared to $250 for CP/M-86. Moreover, DRI was unable to ship CP/M-86 for a full year after the PC's introduction, whereas PC-DOS was not only ready on the day of introduction, the programs IBM sold for the machine ran on it. CP/M-86 never overcame DOS's headstart.

As it turned out, the need for MS-DOS to have CP/M compatibility was not significant. Rather than translate old programs that ran in 64K, most developers wrote new software that took advantage of the increased addressing space of the new IBM machine's operating system. Without it, the power and ease of use of such programs as Lotus 1-2-3, dBASE III and MultiMate would not have been possible. Without that extra addressing space, the IBM PC could not have been the overwhelming success it was.

The Best OS for Picos

For pico machines, however, such power is not always necessary. If a machine's intended tasks are note taking, simple communication via modem, limited number crunching and simple custom applications, the extra expense of more memory and a more powerful processor may not be justified. For many laptop machines, CP/M and a Z80 is just the ticket.

On the other hand, if compatibility with all the software one uses in the personal computer back at the office is called for, MS-DOS and the 8088 is the operating system of choice.

MS-DOS has continued to improve, but many of the improvements are of limited value for today's picos. Versions 2.0 and higher of MS-DOS incorporate a hierarchical file structure that facilitates keeping things straight on a large capacity disk, a need that's less than dire on today's laptop machines, since the power draw and bulk of large capacity hard disks is currently more than can be handled.

Yet, there can be no doubt that MS-DOS has eclipsed CP/M. Although a million CP/M computers have been sold, several million more run MS-DOS. In the world of operating-system specific magazines, it is *CP/M Users Guide* versus *PC*, *PC World*, *PC Tech Journal*, and *PC Week*. In the world of software publishing, the odds are even higher in favor of MS-DOS. And if you need further proof, look no further than to Digital Research's latest operating system, Concurrent DOS: it is MS-DOS compatible. The tables have been turned. ■

Kevin Strehlo is the former coordinator of PC Week's Rumor Central. He is currently a freelance writer specializing in IBM PC-related topics.

Bill Gates, chairman of Microsoft, negotiated rights to Seattle Computer's 8086 DOS for IBM.

The one thing that did dominate personal computing was the CP/M operating system. Nearly every microcomputer used it-even the Apple II. although it required an add-on board with a processor that ran the 8080 instruction set. It seemed unreasonable that even TBM would switch from an industry standard as strong as CP/M.

It was only when Paterson went to work for Microsoft a few months later that he learned it was TBM. But even a1 the introduction of the TBM PC in August 1981, it wasn't clear that the MS-DOS operating system Tim Paterson had written, dubbed PC-DOS by the press - although IBM called it simply DOS-would be important.

IBM introduced the PC with three operating systems-PC-DOS. the p-system and CP/M 86. Even the market research firm, Future Computing, wrote that the most significant aspect of the new machine was that the PC ran CP/M.

But CP/M was not to dominate the personal computing world any longer. and Future Computing quickly changed its tune. Later reports by the Texas-based market research firm rated a new computer largely on a single factor: whether it could run off-the-shelf PC-DOS applications.

Today. while laptop computers remain a stronghold for CP/M. the majority of the action in software development and microcomputer sales has been with MS/PC-DOS machines.

How did it happen? Why did CP/M lose out to MS-DOS? Why is CP/M still important in the world of microcomputers? And what's the difference anyway? Is MS-DOS any better than CP/M?

The best way to answer these questions is to go back to the beginning.

The Birth of CP/M

In 1972, while Gary Kildall was teaching computer science at the U.S. Naval Postgraduate School 1n Monterey, Calif .• he became intrigued with one of the fin.I of a new type of semiconductor part called a microprocessor. Although the four-bit Intel 4004 was too limited 10 do anything useful. Kildall's curiosity was piqued by the idea of a computer on a chip, and he decided 10 visit the Silicon Valley company that was making the things and see what else Intel had cooking.

Kildall and the small group of engineers working on microprocessors at Intel hit it off, and soon Kildall found himself commuting inland from his ocean-side home one day u week to work at Intel. Using a minicomputer 10 simulate Intel's new eight-bit microprocessor, the 8008, Kildall soon had created a version of the PL-I language that ran on it.

Kildall took one of the systems Intel sold as :in aid in developing software for the new microprocessors as partial payment for his work. Although his students at the Institute loved to play with the 8008-based microcomputer (which was soon upgraded with the more powerful 8080 and a high-speed tape reader), Kildall knew it needed real data storage if it was going 10 be truly useful. He did some work for Shugart Associates in 1972 in exchange for one of the early eight-inch floppy disk drives. But Kildall, no hardware ex:expert. failed in designing a controller board to interface the drive with his computer.

It was not until 1973, with John Torode from the University of Washington designing the hardware, that Kildall was able to write a simple operating system to control the transfer of d11a between the computer and the disk drive.

Despite the acronym DOS, which stands for Disk Operating System, there is more 10 such software than the kernel that Kildall had written to control the disk drive. However, Kildall wasn't focusing his attention on fleshing out his operating system kernel. The project he had grcnt hopes for was a microprocessor-based horoscope machine that he and a friend built and installed in Mores nil around San Francisco. Although the work didn't pay off in the anticipated deluge of quarters - the mechanical pan of the machine tended to jmn after ii had printed juM n few horoscopes- it rounded out Kildall's kernel.

When he tacked the software development tools (an editor. assembler and debugger that aided the production of language the microprocessor understood) he had used to develop the horoscope program onto his kernel, Kildall had all the tools needed 10 write and run useful programs.

When Kildall showed his Control Program/ Monitor (CP/M for short) 10 the powers that were at Intel. they said it had no commercial potential. The company thought its microprocessors would end up largely in watches, calculators and appliances. not in the kind of general-purpose microcomputers hobbyists were building.

Thus it was that Kildall, encouraged by his wife Dorothy, formed a company called Intergalactic Digital Research. placed ads in a few magazines and began to sell his CP/M. As the business became more serious, the Kildalls incorporated as Digital Research. Inc. (DR!). Dorothy. to avoid any · 'just his wife·· stigma, began using her maiden name, McEwen. When they sold IMSAI unlimited rights to CP/M for $25,000 in 1977, Digital Research became a full-time enterprise with Gary running research and development and Dorothy hand I ing the business side.

When the ability to utilize a disk drive and i1s Z80 microprocessor (which was faster than the 8080 bu1 ran the same instruction set) gave IMSAI an edge over i1s chief competition. MITS (maker of 1he first commercially successful personal computer. I.he Altair), other emerging microcomputer companies began to make the trek to Digital Research in Pacific Grove, a suburb of Monterey.

Tarbell Electronics. Digital Microsystems, Heath Electronics and the dozens of other companies that licensed the CP/M operating sys1em had good reasons for 1he 1rip. fl was cheaper to license the operating system Kildall hod developed and 1ailor i110 o particular Z80-based microcomputer than it was 10 develop an opera1ing sys1em from scratch. More important. a machine on which CP/M ran could run I.he application programs 1hat had been written for other CP/M machines. The only operating systems in competition with CP/M were limited to a single manufacturer's machine. and so CP/M and the Z80 microprocessor on which it ran became a kind of standard by default.

Not all computer manufacturers offered CP/M. Radio Shack substituted its proprietary TRS-DOS for I.he Z80-based TRS-80 computers, for example. Bu1 many TRS-80 users bought a version ofCP/M tailored for I.he Radio Shack machines by other companies. such as Pickles and Trout, in order to run all the CP/M software.

The most popular personal computer in 1980 was unquestionably the Apple II, which couldn't run CP/M because it was based on the 6502 instead of the 8080 or Z80. Although much credit for the success of Apple's machine has to be given to the first spreadsheet, VisiCalc (which at first ran only on I.he Apple II under Apple's proprietary DOS). many Apple II owners bought an add-on card for their machines 1ha1 included a 2-80 processor. memory and 1he CP/M operating sys1cm. This allowed I.hem 10 run 1he e,·er-increasing pool of business software being written for ORI's operating sys1en1, including WordMar and dBASE U.

The most popular of such cards was the Softcard, developed and sold by Microsoft. In fact. sales of the Softcard were so high that Microsoft became DRI's

largest cus- 101nerf or CP/M. As I9 80 rolled 10a n end. 1h:11fa c1w as soon to take on an ironic twist.

CP/M Upgraded

When IBM decided 10 en1er the microcomputer business. it went to Microsoft on one-day'i. no1icc-for advice on wha1 kind of machine to build and for several key pieces of software. Ga1es had to cancel an appointment with Atari's chairman Ray Kassar in order to meet with mM. but he did it on 1he theory that if IBM was entering the microcomputer business as rumored, Microsoft should do anything it could to be a pan of it- because IBM succeeded at nearly everything it tried.

Microsoft's BASIC interpreter had been an integral pan of nearly every personal computer sold, and Microsoft's other languages were popular among software developers. Microsoft president Bill Gates knew microcomputers and the personal computer market as well as anyone. Thus it was no surprise when IBM asked Microsoft to make a proposal about developing languages for its planned machine and detail what the features of that machine should be.

No, it was no surprise that 1he computing industry veterans listened to president Bill Gates extol the new generation of 16-bit chips and the need for a disk drive- they were thinking of an 8-bit machine with a cassette interface. But it was a bit of a surprise when an mM official responded by asking Gates to sell IBM CP/M as well. Ga1es patiently explained that CP/M belonged to a company 1,000 miles down I.he coast. ORI, headed by Gary Kildall. Ga1es dialed DRI's number and handed I.he phone 10 an IBM representative, who made an appointment for the next day.

Legend has it that Kildall was out on a joyride in his plane when IBM came calling. Actually, Kildall already had an appointment with a customer in Silicon Valley the next day and, unlike Gates. decided to keep it. Af1er all, Dorothy McEwan always handled I.he business end of things with the firm's legal counsel anyway-why should a meeting with IBM be any different?

After concluding his business. Kildall flew back in the late afternoon and joined the meeting in progress, but things weren't going well. McEwan and DRJ's legal counsel Jerry Davis had balked at the nondisclosure agreement TBM had asked them 10 sign, because i1 contained a clause th:11 specified any infom1ation revealed in I.he meeting would become IBM's 10 use as it pleased. Since 1he meeting was about CP/M, McEwan thought such an agreement amounted to giving away the store, and refused 10 sign. The Il3M representatives were on I.he verge of leaving when Kildall arrived.

Kildall, familiar with IBM's way of doing things, knew IBM was an honorable company. The nondisclosure document ,vas meant to protect TBM from lawsuits in the even1 it later marketed similar technology that had been developed independently within IBM . With Kildall's reassurances. the nondisclosure agreement was signed. the meeting proceeded and. according 10 Kildall. went rather well.

Gary and Dorothy, as it happened, were about 10 leave on vacation and had seats on the flight that took the IBM representatives back to Boca Raton, Fla. Discussion continued amiably during the flight, according to Gary, and they agreed 10 get back together after the Kildalls returned from vacation .

It never happened . Bill Gates has said the problem was Kildall' s expression of reluctance to modify CP/M for IBM's requirements; Kildall believed a standard was a standard. lo any case, IBM eventually came back 10 Microsoft and asked if the Bellevue. Wash., firm could do an operating system. as well as the languages. It added only another 10 percent or so 10 the amount of code Microsoft was to write for the new machine; more important. Microsoft knew the operating system under development at Seattle Computer nearly fit the bill . When Microsoft had described that operating sys• tern in writing and IBM agreed it would be fine, provided a few changes were made. Microsoft negotiated rights to Seattle Computer's 8086 DOS.

What Microsoft had really contracted for was the work of a person it knew quite well. Seattle Computer's Tim Paterson had taken the first couple of cracks at designing Microsoft's Z80 Softcard card for the Apple before another engineer finished up. Microsoft was also familiar "'uh Paterson· s latest product. a processor board for scientific and engineering computer s based on the new 16-bit 8086 chip from Intel: Microsoft had used the board while writing its new BASIC for the 8086 and its compatible cousin. the 8088 . The board ""as one of the first implementations of Intel's new chip . It was done so early that the documentation from which Paterson began designing in June was dated Jul y. and talked about five and eight MH z chips when only four MHz chips were available.

The operating system Paterson was writing for his newbboard was to be CP/M compatible so that CP/M programs for the eight-bit Z80 could sim- ply be tranSlated and run unchanged on the new 16- bit 8086 . Paterson had no access to CP/M other than its documentation. however. and used as his chief model the CP ~I look-alike operating system called COOS that ran on the Cromemco [mis-spelled in the article as "Cromenco"] machine they used at Seattle Computing .

Thus it was that some of the improvements of Paterson's DOS over CP/M were accidental. If CP/M encountered an open disk drive door when it was trying to read from a disk. for example. it would crash . Paterson's operating system. like the CP/M look-alike he used as a model. responded to an open door with an "Abort. retry or ignore?" message.

Some improvements were Paterson's idea. however. You could halt a program that was ruMing under CP/~I (and COOS) only by rebooting the machine . Paterson decided the ability to "break" the operation of a program and return 10 the operating system prompt made more sense . He also thought that the need for the PIP utility program to be on the disk v. hen you wanted to copy a file made no sense; nor did the terms PrP and · · =' · 10 describe the action of copying a file. Thus he decided to embed a file copying command with more sensible syntax right into his operating system. And whereas CP/M could destroy files if a user switched disks without telling CP/M such a switch had been made, Paterson made MS· DOS look at the disk in the drive before it v.·rote 10 it 10 prevent such disasters.

Perhaps the key thing Paterson tried 10 do was 10 speed up read and write operations. Borrowing from the compiled BASJC , he had helped Microsoft put on his 8086 board, he made his operating system keep information about files-called FA Ts (File Attribute Tables)-io memory instead of on the disk, which speeded file operations considerably.

It turned out that Paterson's DOS was not perfectly compatible with CP/M. however. because - at least according to Paterson some of the features he copied from CP/ M"s documentation did not work exactly as documented.

The key difference between the operating systems, however. was due to differences between the chips for which they were written. The Z80 processor that CP/M was designed for could address only 64K bytes of memory. while the 8088 and 8086 processors Pater son wrote his DOS for could address one Megabyte (I.OOOK bytes) of memory. IBM. through Microsoft. told Paterson to use only 640K bytes or that memo ry and reserve the remaining 360K bytes for the system's use. Even so. it was hard 10 imagine that programmers would ever need more than a 10-fold increase in memory. It augered much-improved programs for the next generation of personal computers.

This key improvement of Paterson's DOS over CP/M was also a feature of Digital Research's CP/M-86. of course . since it also ran on the more advanced

chips. So why did MS-DOS win?

IBM Picks the Winner

CP/ M-86 was only a plan on a blackboard on that fateful day in 1980 when IBM called on DRJ. Unfortunately. IBM never called back. and Kildall was unaware of the project's process until, shortly before the IBM PC was to be introduced in August of 1981. IBM returned and asked him 10 write an operating system for its new machine. Since demand for the Z80-based CP/M had not abated. not much work had been done yet on CP/t,.1 for the 8086: a team immediately got to work.

In retrospect. it is clear IBM wanted CP/M only as a backup in case its new operating system did not gain support among third party developers. IBM had clearly stacked the cards in its DOS's favor. The price of PC-DOS was $40 compared to $250 for CP/M-86. Moreover. DRI was unable to ship CP/M-86 for a full year after the PC's introduction. whereas PC-DOS was not only ready on the day of introduction. the programs mM sold for the machine ran on it. CP/M-86 never overcame Dos's head-start.

As it turned out. the need for MS-DOS 10 have CP/M compatibility was not significant. Rather than translate old programs that ran in 64K. most developers wrote new software that took advantage of the increased addressing space of the new IBM machine's operating system. Without it. the power and ease of use of such programs as Lotus 1-2-3. dBASE III and MultiMate would not have been possible. Without that extra addressing space. the IBM PC could not have been the overwhelming success it was.

The Best OS for Picos

For pico machines. however, such power is not always necessary . If a machine's intended tasks are note taking. simple communication via modem. limited number crunching and simple custom applications. the extra expense of more memory and a more powerful processor may not be jus tified. For many laptop machines, CP/M and a ZSO is just the ticket .

On the other hand. if compatibility with all the software one uses in the personal computer back at the office is called for, MS-DOS and the 8088 is the operating system of choice.

MS-DOS bas continued 10 improve. but many of the improvements are of limited value for today's picos. Versions 2.0 and higher of MS-DOS incorporate a hierarchical file structure that facilitates keeping things straight on a large capacity disk, a need that's less than dire on today's laptop machines, since the power draw and bulk of large capacity bard disks is currently more than can be handled .

Yet, there can be no doubt that MS-DOS has eclipsed CP/M. Although a million CP/M computers have been sold. several million more run MS-DOS. In the world of operating-system specific magazines, it is CPIM Users Guide versus PC. PC World, PC Tech Journal, and PC Week. In tile world of software publishing. tile odds are even higher in favor of MS-DOS. And if you need further proof , look no further than 10 Digital Research ·s latest operating system, Concurrent DOS: it is MS-DOS compatible. The tables have been turned.

Dr. Dobb's Special Report, Spring 1997

by Michael Swaine

Michael, Dr. Dobb's Journal's editor-at-large, can be contacted at *mswaine@cruzio.com* or http://gate.cruzio.com/~mswaine.

In the early days of the personal-computer revolution, the atmosphere at those shoestring startup companies with names like "Golemics" and "Loving Grace Cybernetics" was often more academic than businesslike. This collegiate ambiance touched everything, from the ways in which decisions were made and respect allocated, right down to sophomoric pranks and styles of dress.

There's a fairly obvious reason for this, or at least for some of it: Microcomputers were a new field, ripe for rapid advances, and that's a situation that fits neatly into a collegial atmosphere in which information is openly shared. When discoveries are freely shared, it's easier to build quickly on those discoveries; conversely, when progress is rapid, there is less reason to hold onto yesterday's discoveries. This natural synergy between rapid progress and information sharing is one key factor in the spectacular growth in the use and acceptance of computers over the past 20 years. It's one of the reasons that the personal-computer revolution really has been a revolution.

In time, companies like Apple and Microsoft would emphasize this synergy, explicitly calling their corporate headquarters "campuses." Even today, computer hardware and software companies often have a lot of the look and feel of grad school. But this predilection for a collegial atmosphere predates Apple and Microsoft. And while it didn't start there either, it was nowhere more evident in the early days than at one of the first personal-computer software companies—Digital Research. Digital Research could hardly have been anything but collegial: The company that gave personal computers their first operating system was the brainchild of a perpetual academic and born teacher. His name was Gary Kildall.

Seattle

Gary Kildall seemed fated to be a teacher. His uncle would later claim that it was what Gary had always wanted. Teaching certainly was in his blood: The Kildall family actually owned and operated a small college. More precisely, it was a school for the teaching of navigation, based in Seattle, Washington. The Kildall College of Nautical Knowledge, the family called it; it was founded in 1924 by Gary's grandfather. Many Kildalls taught or worked at the school, including Gary himself for a while, after graduating from high school.

including Gary himself, for a while, after graduating from high school.

But he had decided that year that he was going to be a math teacher, so he enrolled at the University of Washington. Newly married to high-school sweetheart Dorothy McEwen, he buckled down and applied himself to his studies, trying to put a childhood of mediocre grades, fast cars, and pranks behind him.

Somewhere along the way to a math degree he got hooked on computers. On finishing his degree, Gary went on to graduate school in computer science. He was still headed for a career in teaching, only now it would be teaching computer science at one of the few colleges that had programs back then. But there was a hitch. He had joined the Naval Reserve, and it was the '60s, with the Vietnam war in full flower. The Navy gave him a choice: Go to Vietnam or take a faculty position at the Naval Postgraduate School in Monterey, California.

Gary thought about it for a microsecond and chose Monterey. Even when the Navy told him what to do, the answer was the same: Teach.

Monterey

It was in Monterey that Gary created CP/M, the program that brought him success and that became the unquestioned standard operating system throughout the microcomputer industry. CP/M was a good product and deserved, for many technical reasons, to be the standard. But getting there first always helps, too. And CP/M actually appeared a year before the first commercial microcomputer arrived on the scene.

Unlike operating systems before and since, CP/M was not the result of years of research by a team of software engineers. It was, like most software of its time, the invention of one individual. That individual was Gary Kildall, and if chance put Kildall in just the right place at just the right time, you would have to say, in retrospect, that chance chose well. As it did with Bill Gates, chance spoke to Gary Kildall through a note on a college bulletin board, college bulletin boards apparently being the Schwabb's Drug Store of personal-computer fame.

The note talked about a $25 "microcomputer," a pretty good deal even at 1972 prices. It was actually describing not a computer but the first microprocessor, the 4004 that Ted Hoff had designed at Intel. Presumably, this note was an advertisement torn from a recent issue of *Electronics News*. Intel had hired Regis McKenna to write the ad at Hoff's urging. Hoff was convinced that techies would see the virtue of this new device, this general-purpose processor, and urged that it be advertised, extravagantly but not altogether inaccurately, as a "microcomputer." This would make it absolutely clear that it was not just another limited-purpose device, but something fundamentally different. Hoff was sure that engineers and programmers would get it.

Kildall got it, literally, sending off his $25 for one of the first Intel 4004 chips.

It was 1972. Kildall was busy teaching computer science at the United States Naval Postgraduate School in Monterey. He and Dorothy (and son Scotty) had moved into a house in neighboring Pacific Grove. The Seattle natives loved this scenic coastal town, with its laid-back, fog-draped ambiance. The place suited the easy-going professor. Whether in class or among family and friends the lanky, shaggy-maned Kildall spoke with the same soft voice, the same disarming wit. Although he was teaching at a naval installation, he wouldn't have been out of place on any college campus in his customary sport shirts and jeans. When he had a point to make he would often cast about for chalk or a pencil; he was an incurable diagram drawer.

Gary was happy in his marriage, happy to be living by the ocean, happy not to have gone to Vietnam, and most definitely happy in his job. He loved teaching, and the work left him time to program. Nothing in his life was preparing him to run a business, to handle a spectacularly successful software company supplying the essential software for hundreds of different computer models in an industry running wild. Everything argued for his staying right where he was forever, teaching and programming. At first, the 4004 seemed to fit in with that scenario.

Gary started writing programs for the 4004. His father, up at that little navigation school in Seattle, had always wanted a machine that would compute navigation triangles. Gary made that his project, writing some arithmetic programs to run on the 4004, thinking idly that he might come up with something that his father could use. He was really just fooling around with the device, trying to see how far he could push it, and with what speed and accuracy.

Not all that far, he soon learned. The 4 in 4004 meant that the device dealt with data in 4-bit chunks—less than a character. Getting anything useful done with it was a pain, and performance was pitiful. Although he was frustrated by the limitations of the 4004, he was fascinated by what it promised. Early in 1972 he visited Intel and was surprised to see how small the microcomputer division (dedicated to the 4004 and the new 8008) was: The company had set aside only a few small rooms for the entire division. Gary and the Intel microcomputer people got along well, though, and he began working there as a consultant on his one free day a week. He spent months programming the 4004 in this day-a-week mode until he "nearly went crazy with it." He realized—and it was a radical idea for the time—that he would never go back to "big" computers again. Which is not to say that he stopped using "big" computers. With both the 4004 and the significantly more powerful 8008 that he soon moved on to, he was doing his development work on a minicomputer, much as Bill Gates and Paul Allen did later in writing software for the breakthrough MITS Altair computer. Like Paul Allen, he wrote programs to simulate the microprocessor on the "big" minicomputer, and used this simulated microprocessor, with its simulated instruction set, to test the programs he wrote to run on the real microprocessor.

But unlike Gates and Allen, Gary had the benefit of a development system, essentially a full microcomputer spun out around the microprocessor, so he could try out his work on the real thing as he went along. In a few months he had created a language implementation called "PL/M," a version of the mainframe language PL/I that was significantly more sophisticated than Basic.

The Lab

As partial payment for his work, Gary received a development system of his own, which he immediately set up in the back of his classroom. This allowed him to combine his new obsession with microcomputers and his love of teaching. The system in the back of the classroom became the Naval Postgraduate School's first—if not the world's first—academic microcomputer lab.

And academic it was. This was not just Gary's toy; he used it to teach students about the technology, and encouraged them to explore it. His curious students took him up on it, spending hours after class tinkering with the machine. When Intel upgraded this Intellec-8 from an 8008 to its new 8080 processor and gave Gary a display monitor and a high-speed paper tape reader, he and his students were working with a system comparable to—favorably comparable to—the early Altair computer before the Altair was even conceived.

Gary realized, though, that he was missing an essential ingredient of a really useful computer system—an efficient storage medium. In the early '70s, paper tape was one of the standard storage media, along with the infamous punched card. Neither was very efficient, and the issue was particularly critical on microcomputer systems because the relatively slow microprocessors couldn't offset the inherent slowness of the mechanical process of punching holes in

pieces of paper.

IBM had recently introduced a new storage medium that was much faster and more efficient. It was based on the existing technology of recording data as patterns of magnetization on large rapidly spinning disks, a medium that had everything going for it except price. But IBM engineers figured out how to scale down this technology to something smaller and more affordable, creating the floppy-disk drive.

One $5 floppy disk held as much data as a 200-foot spool of paper tape, and a floppy-disk drive could be had for around $500. The combination of the microprocessor and the floppy disk drive meant that, in Kildall's words, "It was no longer necessary to share computer resources." In other words, the elements of a personal computer were at hand. Well, most of the elements. Gary soon found that some important components were still annoyingly missing.

By this time, an industry was developing to create these floppy-disk drives in volume, and Shugart was the pioneer of this industry. Once again, Gary traded some programming for some hardware, getting himself (and the microcomputer lab) a Shugart disk drive. But for the disk drive to work with the Intellec-8, another piece of hardware was needed, a controller board that fit in the Intellec-8 and handled the complicated communication between the computer and disk drive. This piece of hardware, unfortunately, did not exist.

Gary tried his hand more than once at building the controller. When that proved more challenging than he expected, he explored the idea of using a different magnetic medium—ordinary audio tape, mounted on a conventional tape recorder. His efforts in interfacing a tape recorder with the Intellec-8 were no more successful than his efforts to build a disk controller. It soon became clear that his considerable programming expertise was no substitute for the hardware knowledge needed to build a device that would connect the Intellec-8 with an efficient storage device. It is worth noting that Kildall was well ahead of his time: When MITS, IMSAI, and other companies began marketing microcomputers, they began with paper-tape or magnetic-tape storage. It would be several years yet before disk drives came into common use on microcomputers.

Finally, in 1973, admitting hardware defeat, Gary turned to an old friend from the University of Washington, John Torode. Torode would later found his own computer company, but in 1973, he was just doing a favor for his old friend. "John," Gary said, "we've got a really good thing going here if we can just get this drive working." Torode got the drive working.

Entrepreneur

Meanwhile, Gary found himself involved with another hardware engineer on another microprocessor-based project. This project, for all its apparent frivolousness, was the first hint of any genuine commercial ambitions on the part of Gary Kildall. The project was the ill-fated Astrology Machine.

Ben Cooper was a San Francisco hardware designer who had worked with George Morrow on disk systems and later would, like Torode, start his own computer company, Micromation. In the early '70s, he thought he could build a commercially successful machine to cast horoscopes, and he enlisted Gary's help.

The business was not a success—"a total bust," Gary later called it. Still, the Astrology Machine gave Gary the first field test of several programs he had written and rewritten over the past months: a debugger, an assembler, and part of an editor. He also wrote a Basic interpreter that he used to program the Astrology Machine. Since, for Gary, there was little distinction between his academic work and his commercial or consulting work, he passed on the tricks he came up with to his students. He passed the tricks he came up with in writing the Basic interpreter on to a young naval officer named Gordon Eubanks (today, president and CEO of Symantec). All the programs, with the exception of the interpreter, became part of the disk operating system he was writing to control the controller that Torode was building.

CP/M

As they worked on the hardware and software to make the computer and disk drive work together, Kildall and Torode traded thoughts on the potential of these microprocessors. Neither of them thought that the computer system in the back of Gary's classroom would have a very large market. Microprocessors, they thought, as most everyone at Intel itself thought, would see their chief use in smart consumer devices, like blenders and carburetors. Kildall and Torode did see a small market for development systems like the Intellec-8, but only among the engineers who would be designing and developing those smart blenders and carburetors. This view was fostered by Intel management. In fact, Intel's top brass was even more conservative about the potential market for the devices than Kildall. When Gary and some Intel programmers wrote a game that ran on the 4004 and suggested that Intel market it, Intel chief Bob Noyce vetoed it. The future of microprocessors was elsewhere, he told them; "It's in watches."

When Intel passed on marketing the game, Gary wasn't fazed. He more or less agreed with Noyce about the market. But when the company turned down a piece of software closer to Gary's heart, he began to think that he might have a better sense of the value of microcomputer software than the powers-that-be at Intel.

When Torode finished the controller, Gary polished the software to control it. This was a disk operating system, the first such for a microcomputer, and Gary called it CP/M, for "Control Program/Monitor" or "Control Program for Microcomputers." He presented it proudly to Intel and suggested a reasonable price for it: $20,000. Intel passed. The thinking, apparently, was that the target market for Intel development systems was people like Gary, and since Gary had written some impressive software for the 4004, 8008, and 8080 without an operating system, clearly an operating system was not necessary for the target market. Not $20,000 necessary, anyway. Intel did buy Gary's system programming language, PL/M, but not CP/M.

Gary had been doing his consulting and development work under the name "MAA," or "Microcomputer Applications Associates." MAA (that is, Kildall) completed CP/M in 1974. It was a spartan system, containing only what was essential. It was also remarkably simple, reliable, and well suited to the limited microcomputers of the day. Gary believed in CP/M, and if Intel didn't want it, he was sure there were a lot of hardware hackers and engineers who would. He could sell it himself.

DRI

Gary might have been content to run a small ad in the back of one of the electronics magazines, maybe putting a note on that bulletin board. What actually ensued was a little more ambitious. At Dorothy's urging, the Kildalls formed a corporation. Gary would do the programming and Dorothy would run the business. She started using her maiden name, McEwen, so she wouldn't be seen as just "Gary's wife." They incorporated, dropping the MAA name and calling their corporation "Intergalactic Digital Research Inc." This was later shortened to Digital Research Inc. And they started selling CP/M.

It was the beginning of the personal-computer revolution. (Everything Gary had been doing up to then was prerevolution.) The Altair had been announced,

and a flock of other startup companies were starting work on microcomputers, usually kits but sometimes assembled systems, some with a paper tape interface but many with no satisfactory provision for data storage. They needed disk drives, and they needed a disk operating system.

In those days, there was no model for software pricing, so Digital Research's first customers got some pretty good deals. When Tom Lafleur came to them wanting a license for his company, GNAT Computers, Dorothy gave him unlimited rights to use CP/M as the operating system on any product his company produced, for a whopping $90. Within a year the price had gone up by a factor of 100.

The deal with IMSAI in 1977 was the turning point, and Dorothy knew it. Until 1977, Digital Research was, like most of the industry, little more than a hobby. And until 1977, IMSAI had been purchasing CP/M from Digital Research on a single-copy basis. But IMSAI, with its grandiose plans to sell thousands of floppy-disk-based microcomputers for use in businesses, wanted to restructure the deal. Marketing director Seymour Rubenstein (later of WordStar fame), a shrewd negotiator, haggled with Dorothy and Gary, ultimately arriving at a license fee of $25,000. Rubenstein gloated. He felt that he had virtually stolen CP/M from them. He respected Kildall's programming expertise, but thought the Kildalls were babes in the woods when it came to business. Perhaps they were, but the Kildalls' perspective was a bit different. After the IMSAI deal, Digital Research was a real, full-time business. The IMSAI deal also solidly established CP/M as the standard, and other companies followed IMSAI's lead in licensing it. CP/M quickly became and remained so solid a standard that, until IBM introduced a personal computer, Digital Research faced no serious competition.

And the programmers who would provide that competition were still working at MITS in Albuquerque.

Success

After the IMSAI deal, Digital Research began to grow rapidly. Although it wasn't a financial necessity, Gary continued to teach at the Naval Postgraduate School for years after the founding of DRI. DRI itself felt very academic. Relationships tended to be collegial, the atmosphere casual, discussions animated and cerebral. Or not so cerebral: The atmosphere sometimes was less like a college classroom than a college dorm. Gary liked to rollerskate through the halls, and once conducted an employee interview in a toga.

The staff was young, eager and deeply loyal.

"Gary built a campus in Monterey," Alan Cooper would later remember. DRI "was collegial in every respect." It was only when the company didn't function like a college that Gary got frustrated. Employees would come to him expecting him to solve business problems, marketing problems, personnel problems. He didn't know the answers; didn't really want to think about the problems. What he wanted to do was write code. "Code was his element," Cooper says.

So he wrote code, keeping out of the business end of things as much as possible. He improved CP/M, making it more portable. Certain features of the program were logically independent of the hardware, while others were intimately dependent on the exact features of the machine the program was running on. Gary shrewdly carved out the smallest possible set of machine-dependent elements, and made them easily field customizable. The result was that DRI could write one version of CP/M, and hardware vendors, field engineers, or whoever could customize it to their particular hardware configuration. This approach would be reinvented years later as the "hardware abstraction layer," but Gary had it down cold in 1978.

Even his second-in-command was—let's not mince words—a total code geek. Tom Rolander was exactly the sort of person Gary liked to have around him: just a kid in a candy store when it came to programming, without a business bone in his body. There weren't many business-boned bodies at DRI. But the company did have the operating system that you pretty much had to run on your computer system. It had the market because it had the technology.

DRI didn't actually have the entire market. In the early '80s, the Apple II was the largest-selling machine that did not run CP/M, but it was also the largest-selling machine, period. The base of software for CP/M systems was large and growing, and Microsoft, seeing an opportunity, made an uncharacteristic move into hardware: It developed a SoftCard for the Apple II that would let it run CP/M. Then it licensed CP/M from DRI to sell with the SoftCard. Soon Microsoft was selling as much CP/M as DRI.

Doubts

Gary had moments of doubt about whether this was what he wanted to be doing with his life. In one of the darkest of those moments in the late '70s, Gary passed the parking lot by on his way in to work, and continued around the block, realizing that he just couldn't bring himself to go in the door. He circled the block three times before he could force himself to confront another day at DRI.

Later, in frustration, he offered to sell the company to friends Keith Parsons and Alan Cooper. Parsons and Cooper were running one of the first companies to deliver business software for microcomputers, a kitchen-table startup named "Structured Systems Group." Gary was fed up with all the pointless games and distractions of business. They could have the whole operation for $70,000, he told them. As for him, he would go back to teaching.

It was a dream: There was no way it would have happened. Keith and Alan had little hope of coming up with $70,000, and Dorothy would never have okayed the deal. Dorothy's self-taught business skills would be sorely tested in the near future, but in the late '70s, she knew well enough that the Kildalls had something worth a lot more than $70,000 in DRI. By 1981, it was obvious to the dullest wit that she was right: In that year, there were some 200,000 microcomputers running CP/M, in more than 3000 different hardware configurations, a spectacular testament to the portability that Gary had designed into CP/M. That year, the company took in $6 million. Digital Research employed 75 people in 1981 in various capacities. It had come a long way since its inception only seven years earlier in Gary and Dorothy's house.

That was also the year that IBM announced its plan to build a personal computer.

The story has been told often—and variously—of how Digital Research lost the IBM operating-system contract to Microsoft, and how this made Microsoft's success. It had a big impact on DRI, too.

Multitasking

From that point on, DRI was going in several directions at once. DRI was one of the first personal-computer companies to seek venture-capital funding to go public. The VCs were willing, but insisted that strong management be brought in to get the business under control. Gary was thrilled by the idea of bringing in someone on whom he could unload all the annoying business decisions. John Rowley got that job. Gary quickly disappeared into the fold of Tom Rolander and the developers, and was rarely seen elsewhere. In particular he was rarely seen with John Rowley.

Personable, bright, enthusiastic, Rowley nevertheless struck some around him as just a bit unfocused. He was routinely late to meetings, and he called a lot

of them. If there was an overall strategy to his actions, it wasn't obvious. Sometimes, one employee later recalled, he forgot to pay his bills—his own bills, that is—and dunning letters would find him at work. He was boundlessly enthusiastic, but as company direction shifted from week to week, the optimism got old quickly.

But Rowley may very well have been doing the best anyone could under the circumstances. The circumstances being that the company remained Gary's company, and actions Gary took or authorized could drive the company into one market or another. And did.

Gary wrote a version of the programming language LOGO for his son Scott. He just thought it would be a cool thing and that Scott could learn about programming and logic from it. Then he handed it to Rowley, saying, what should we do with this? And that was how DRI LOGO became a product. Tom Rolander was fascinated with the Apple LISA (the slo-ow predecessor to the Mac), and set one up in his office. He messed with it for quite a while, but nothing ever came of that. Fortunately. Gary was also intrigued by the LISA/Mac user interface, and began exploring that realm. The company's focus was supposed to be operating systems, but the result of Gary's interest in user interfaces was that one of the many varieties of CP/M then under development got sidetracked into a user-interface shell that would sit atop an operating system. That was "GEM," a Mac-like UI for non-Mac computers. Apple thought it was a little too Mac-like and threatened to sue, and DRI caved. It couldn't have been lost on Gary that Microsoft, which also had a Mac-like UI called "Windows," did not (then, at least) get sued.

The company was making lots of money at first, but it was also making some serious mistakes. Not keeping customers happy was one of the worst. DRI in the early '80s occupied a role similar to Microsoft in the '90s: Everybody depended on it and resented it for that. But DRI just wasn't sufficiently responsive to customer complaints and requests.

Alan Cooper blames Gary. When anyone would tell Gary that he ought to add a particular feature, "Gary would try to argue you out of it." He didn't want to pollute good code with kludged-on features. The PIP command exemplified his attitude. In CP/M, you "Pipped" to drive B from drive A; in MS-DOS, you "Copied" from A to B. Gary thought that there was nothing wrong with using the command PIP to copy, and that any halfway intelligent person could master the concept that you copied (or pipped) from right to left. Bill Gates let people do it the way they wanted. "That difference in attitude," Cooper says, "is worth twenty million dollars." Gary didn't care. What Gary was interested in was inventing.

On Cooper's first day at DRI, he recalls, Gary took him to Esther Dyson's high-level industry conference. "He gave me John Rowley's badge, and we climbed into his Aerostar and flew [to Palm Springs]. I remember running into Bill Gates and saying I had just joined Gary Kildall in research. I said I was working in research and development. He chuckled that Gary had set up an R&D department. He considered R&D to be part of what everybody did. Bill was right."

Gary, however, wanted to segregate R&D from the mundane concerns of the business. He wanted a skunkworks, a small crew that pursued projects on the basis of interest, just as pure academic researchers follow the interesting idea rather than worry about someone's bottom line. And he did.

Some good ideas came out of the skunkworks, although the best mostly came from Gary. He did groundbreaking work on CD-ROM software and on interfacing computers and video disks. A company, KnowledgeSet, came out of that work. So did a CD-ROM-based Grolier's Encyclopedia, a product that showed everyone how to do CD-ROM content. Microsoft's later enviable position in the CD-ROM content market owes a lot to Gary Kildall's good ideas and Bill Gates' ability to spot a good idea and pounce on it.

In the midst of the rest of the confusion, Gary and Dorothy split up. It was more than a private, personal matter, since both of them stayed at DRI. So did the other woman. The atmosphere grew more tense than it already was.

Fame

As Digital Research floundered and flailed, Microsoft flourished. Sometimes Microsoft flourished in ground cleared by Gary Kildall, as in the case of MS-DOS, as in the case of multimedia/CD-ROM technology. The legend of Bill Gates as the technological genius who invented everything in the personal computer realm grew, while a dwindling percentage of computer users had even heard of Gary Kildall.

Kildall was always gracious about this.

At least publicly he was gracious. Inwardly, he hid a bitterness that few ever saw. One day, though, Cooper got a glimpse of Gary's depth of feeling about proper credit for invention.

"Kildall took me aside once, about '83. [He started] talking about Apple. He opened this door, and I saw the bitterness: 'Steve Jobs is nothing. Steve Wozniak did it all, the hardware and the software. All Jobs did was hang around and take the credit.'" Cooper was not blind to the implications of this. Kildall resented that Gates, this dropout, this businessman, was getting credit for things that Kildall had invented. "All of a sudden there was this cauldron of resentment. It must have tortured Gary that Bill Gates [got all the credit]."

Whether Kildall's resentment of Bill Gates was fair or not—and it is important to repeat that it was never publicly expressed—it was probably inevitable. When you look at the allocation of credit in the computer industry from a collegial, academic perspective, it does seem that Bill Gates and Microsoft have, now and then, got credit that rightfully belonged to others. It's hard to defend the idea that this is the right perspective to use in looking at an industry, but a collegial, academic perspective was exactly the perspective from which Gary Kildall viewed his world. He could hardly help but feel wronged.

Austin

Gary never went back into academia, staying with DRI to its end, when it was sold to Novell in 1991. At Novell, all traces of DRI products and projects quickly dissolved and were absorbed like sutures on a healing wound.

Gary then moved to the West Lake Hills suburb of Austin, Texas. The Novell deal had made him a wealthy man. His Austin house was a sort of lakeside car ranch, with stables for 14 sports cars and a video studio in the basement. He owned and flew his own Lear jet and had at least one boat. In California, he kept a second house: a mansion with a spectacular ocean view on 17 Mile Drive in Pebble Beach. He started a company in Austin to produce what he called a "home PBX system," called "Prometheus Light and Sound." He did charitable work in the area of pediatric AIDS. It should have been a good life, but all was not sublime. His second marriage was ending in divorce, and there were signs that lack of credit was continuing to eat at him.

Then, while in Monterey in 1994, Gary Kildall died from internal bleeding on July 11, three days after falling down in the Franklin Street Bar and Grill in downtown Monterey. He was 52.

.

Legacy

And there the history of Gary Kildall and Digital Research ends. But it is more than mere politeness to say that a legacy remains. In March, 1995, the Software Publishers Association posthumously honored Gary for his contributions to the computer industry. They listed some of his accomplishments:

- He introduced operating systems with preemptive multitasking and windowing capabilities and menu-driven user interfaces.
- Through DRI, he created the first diskette track buffering schemes, read-ahead algorithms, file directory caches, and RAM disk emulators.
- In the 1980s, through DRI, he introduced a binary recompiler.
- Kildall defined the first programming language and wrote the first compiler specifically for microprocessors.
- He created the first microprocessor disk operating system, which eventually sold a quarter million copies.
- He created the first computer interface for video disks to allow automatic nonlinear playback, presaging today's interactive multimedia.
- He developed the file system and data structures for the first consumer CD-ROM.
- He created the first successful open-system architecture by segregating system-specific hardware interfaces in a set of BIOS routines, making the whole third-party software industry possible.

That's a good list, as far as it goes. But friends and students might make a different list, citing his gift for explaining, his patience, his high standards in his work, his generosity. Those who knew him in later years in Austin might cite his pediatric AIDS work.

These things are worth remembering, and represent a real positive impact on the world, whether remembered or not.

As for Kildall's place in computer history, it certainly shouldn't be as The Man Who Wasn't Bill Gates. "It was" as his friend and colleague Alan Cooper puts it, "Gary's bad luck that put him up next to the most successful businessman of a generation. Anyone is a failure standing next to Bill Gates."

He was by any measure an admirable man, a business success, an inventor of importance, a humanitarian.

And, above all, a teacher. "When *Fortune* magazine writes about Gary Kildall," Cooper said, "they don't see him in his natural habitat: a university." Kildall was never happier than when he was in that academic habitat, solving tough problems and sharing the solutions that he discovered openly with others.

He should have stayed in academia, a relative later said. It's what he loved. But in a sense, he never really left.

The true story or ... Gary Killdall, inventor of the smart phone

by George Wenzel

I try to tell Gary's story to anyone that will listen. I tried to have everything I know about Gary added to the Wikipedia page, and there I was out voted... If it is reported in the press, it has more weight than if someone that was there reports what really happened.

Remember the story about Gary flying his plane instead of meeting with IBM when they were wanting to put CP/M on the PC? And how missing that meeting caused IBM to go with msdos?

That story is rubbish.

The PC was shipped with a crappy, buggy version of msdos, because msdos was cheap. The user was expected to pay $250 for CPM if they wanted to run the current commercial software (wordstar and others). CP/M was an upgrade path for the PC. The real story was that IBM thought of CP/M as the "good stuff" and it was a premium offering. But that isn't even a tiny part of the whole story...

Did you ever own an original IBM AT? On the IBM AT, the power-up post routine printed the words "AT Multiuser System" at the top of the screen during power up. What the heck is the AT Multiuser System??? The AT prototypes didn't boot msdos, they booted a secret new OS. This new OS (I don't know the code-name for it) was a multiuser dos. The design was simple, you buy an AT, and it comes with one or more 8 port serial cards. You buy Wyse terminals (the ones with the PC Emulation mode(as opposed to modes like VT100 emulation)) and put one one each desk, then you run serial cables to your AT. This OS was a true multitasking OS, and the AT was a small cheap minicomputer. THAT was what the AT was designed to be. Period.

So what the heck happened?

IBM had a successful project, the first manufacturing run filled the warehouse, the software was ready, and it was time to start packaging the retail boxes. The first of the manufactured systems used up the last of the initial supply of 286 chips, before Intel switched to a lower-cost run of the 286 chips. The new 286 chips had some minor changes to increase yields, allowing the price to be lowered. Apparently the yields were low on the original version that IBM started manufacturing with. At some point IBM found a bug in the OS that slipped through the QA tests... It was a subtle bug that only had an impact when the machine was multitasking with multiple users, and as it turns out it was only present on the systems with the new 286 chips.

There was a lot of finger pointing and hand-wringing going on over it. Something was broken in the protected mode functions. IBM sales execs were either going to have to insist Intel use the more expensive low-yield version of the 286 chip, OR IBM was going to have to scrap the multiuser system. IBM is managed by the sales department. Someone in sales did the math... we use the expensive 286 chip, and sell one AT to each customer's office of 15 to 20 people... OR we sell them 15 or 20 machines with a cheaper chip. Which makes more money? It was decided that scrapping the multiuser system would increase system sales volume in theory. Even if the 15 to 20 machines were PC's instead of AT's, more money was made selling more systems than selling one.

So what happened to the multiuser system? The 8-port serial boards were ground into dust, except for a few units that escaped with the beta testers (I used to have a bunch of these). The Wyse terminals still had the PC emulation mode, but the expected sales volume of those never happened, so Wyse suffered as their R&D investment in the project was scrapped. DR got paid for their work on the OS, but they never got to see any revenue from sales. Bill Gates went

from being a footnote in history to being who he is today. The first widely distributed multitasking OS never saw the light of day for several more years, and Gary went from being the grandfather of the small computer industry to a footnote. The operating system sat on a shelf for a couple years, but was dusted off and used when IBM started developing scanner cash registers. The new cash registers needed some sort of network or centralized computer, so DR got to sell a couple hundred copies of an OS that was supposed to sell millions (billions by today). The software got a new name, ConcurrentDOS.

Did Gary miss an IBM meeting because he was flying a plane, sure, he missed meeting all the time because travel prevented timely arrival. He was a pilot, and liked to fly, and sometimes that caused travel delays. Did that meeting cause Bill Gates OS to win over CP/M, not even close!

In engineering circles, there is a great deal of secrecy with regard to un-released projects. The press had no way to know the real story back then. Some low-level IBMer may have been aware of a missed meeting, and made a connection (that didn't exist) between that and the fact CP/M was not dominant, and leaked that to the press. That may have even become the semi-official story being as the real story was secret. But you and I have more proof that my version of the story is true, than the press have that their story is true. I don't have my boxed set of ConcurrentDos any more (it was lost along the way) but you have a copy of it in your archive... and there are probably more than one IBM AT around that still displays the AT Multiuser System banner... ConcurrentDos went on sale to the general public as soon as 386 chips were available, as they had a properly working protected mode. But by then it was too late, IBM didn't want to sell cheap minicomputers any more, and the whole industry had already grown accustomed to msdos.

If Intel hadn't broken the 286 chip, Microsoft would be remembered as the company that wrote software for the Apple II. I purchased my first copy of CP/M from Microsoft... they were selling a z80 board for the Apple, and shipping it with a copy of CP/M. That would have been my last memory of Microsoft, I would have never heard the name Bill Gates, and we would have had several generations of multitasking and graphical interfaces years earlier than the ones Microsoft eventually created. Gary already had the graphical OS, it would have just dropped it on top of ConcurrentDos.

This is just one of the stories I have, the others are more widely known... But the story of ConcurrentDOS and the AT Multiuser System goes untold. That story had a big impact on Gary. He died a rich man, but he also dies a defeated man. Bill Gates and Microsoft's anti-competitive activities haunted Gary. He didn't like talking about it much, he preferred to innovate something better, with the hope of securing a technology patent that would reestablish his deserved status. He did create the next killer app, but he died too soon to finish the push to get it into the hands of the public.

I have two of my prototype wire-wrap boards used in the Intelliphone project, as well as one of the first printed circuit prototypes. I'm the only one that knows how it was supposed to work, because I'm the one that designed it, and I never documented my hardware beyond schematics and verbal meetings with the engineers and customers. Gary should have patented his UI. We should have also patented my memory design.

The Intelliphone hardware consisted of a board called the PPU, and a PC. The PC was mainly used to program the PPU, and serve to hold a bunch of PPU's to form a communications mainframe to be located in telco central offices. The PPU was also designed to be packaged into a single chip, and located in a cell phone. The PPU did not do RF, the RF component was considered transient technology, and expected to frequently change with different phone networks. The PPU was the computer and interface controller for the phone. The PPU was also a subsystem inside the central office mainframe. In the mainframe, the PPU's resided on a PC bus, but the PC was just a power supply and file server to the PPUs. The PC could not transfer data fast enough for the application, so an additional bus was designed into the PPU. The PPU's had two communications paths in addition to the pc bus. The PPU bus consisted of multiple T1 lines, and a shared memory path. The shared memory path was essentially a crossbar memory switch. The crossbar switch allowed large blocks of data to be transported from PPU to another instantly, without wasting time on the PC bus. The T1's carried internal voice data, allowing 12 PPU's to have full duplex voice paths between them for each T1, and the design allowed as many T1's to be added as needed for the size of mainframe being built. My crossbar memory switch was actually more complex than a "simple" crossbar switch, as the intent was to have other capabilities such as blocks of memory that are "broadcast" to multiple CPU's, in addition to more simple bank switching that most crossbar switches do. But my hardware design was dependent on the software engineers writing software to make use of it. The prototypes only memory switched between two PPU's, so much of the memory design went unimplemented because I quit before any large mainframe systems were prototyped.

2014 (Feb 26) - Computer History Museum - blog - "GARY KILDALL AND THE 40TH ANNIVERSARY OF THE BIRTH OF THE PC OPERATING SYSTEM" (By David Laws)

See [HI001O][GDrive]

Late one afternoon in the fall of 1974, in the sleepy California seaside town of Pacific Grove, programmer Gary Kildall and electronic engineer John Torode "retired for the evening to take on the simpler task of emptying a jug of not-so-good red wine … and speculating on the future of our new software tool". [1] By successfully booting a computer from a floppy disk drive, they had just given birth to an operating system that, together with the microprocessor and the disk drive, would provide one of the three fundamental building blocks of the personal computer revolution. While they knew it was important, neither realized the extraordinary impact it would have on their lives and times.

EARLY DAYS

Gary Arlen Kildall was born to a family of Scandinavian descent in Seattle, Washington in 1942. His inventive skills flourished in repairing automobiles and having fun, but suffered in scholastic pursuits. He qualified for admission to the University of Washington based on his teaching experience at the family owned Kildall Nautical School rather than his high school grades.

In 1963, Kildall entered college and married his high school sweetheart Dorothy McEwen, who supported him in his studies. He was one of 20 students accepted into the university's first master's program in computer science. Here his mathematical talents were applied to a subject that fascinated him, all-night sessions programming a new Burroughs B5500 computer. To avoid the uncertainty of the draft at the height of the Vietnam War, on graduating with a PhD he entered a U. S. Navy officer training school and was posted to serve as an instructor in computer science at the Navy Postgraduate School (NPS) in Monterey, California.

CONSULTANT TO INTEL

Kildall remained at NPS as an associate professor after his tour of duty ended in 1972. He became fascinated with Intel Corporation's recently introduced 4004 microprocessor chip and simulated its operation on the school's IBM mainframe computer. This work earned a consulting relationship with Intel where Hank Smith of the Microcomputer Systems Group commissioned the development of PL/M, a high-level Programming Language for Microcomputers that served the company for decades.

To enable software development for Intel's second generation 8-bit device, the 8080, Kildall needed to connect the chip directly to a new 8" floppy disk-drive storage unit from Memorex. Using PL/M, he wrote the prototype code for his Control Program for Microcomputers (CP/M) in a few weeks. (It was later tuned and rewritten in 8080 assembly language.) His own efforts to build the complex electronic circuitry required to physically transfer the data failed and the project languished for a year. Frustrated, he called John Torode, a college friend then teaching at U.C. Berkeley, who crafted a "beautiful rat's nest of wirewraps, boards and cables" for the task.

"ONE OF THE MOST EXCITING DAYS OF MY LIFE"

Working in the tool shed behind his home in Pacific Grove, Kildall "loaded my CP/M program from paper tape to the diskette and 'booted' CP/M from the diskette, and up came the prompt: *. This may have been one of the most exciting days of my life, except, of course, when I visited Niagara Falls," [2] he exclaimed, "We now had the power of an IBM S/370 [mainframe computer] at our fingertips." [1] This is going to be a "big thing" they told each other. There is no record of the precise date of this event, but Torode recalls that it was before he moved to Chicago in the fall of 1974. [3]

As Intel expressed no interest in CP/M, Kildall was free to exploit the program on his own. Torode refined the "rat's nest" and produced a complete floppy disk controller system. The first commercial licensing of CP/M took place in 1975 with contracts between Torode's company, Digital Systems, and Omron of America. Kildall continued teaching part time at NPS and in 1976, with his wife Dorothy as co-founder, they established a company called Intergalactic Digital Research. They shortened the name to Digital Research Inc. (DRI) after a couple of years.

Glenn Ewing, a former NPS student, approached DRI with the opportunity to license CP/M for a new family of disk subsystems for microcomputer maker IMSAI, Inc. Reluctant to adapt the code for another controller, Kildall worked with Ewing to split out the hardware dependent portions so they could be incorporated into a separate Basic Input Output System (BIOS). This allowed all 8080 and compatible microprocessor-based computers to run same the operating system on any new hardware with trivial modifications that could be accomplished by the designer in a couple of hours.

According to John Wharton, Intel's technical liaison to DRI who became a DRI contractor and a friend of Kildall, this was "perhaps Gary's most profound contribution … All previous computer software had targeted specific hardware environments. Gary isolated the system specific hardware interfaces of his OS within a set of "basic I/O system" routines, so it and all applications code would be fully machine independent. This idea created the third-party software industry by expanding the potential market several orders of magnitude." [4]

Gordon Eubanks, who was a student of Kildall's at NPS, identifies another significant contribution: "While I think separating out the BIOS was very important, to me the actual breakthrough was the dynamic relocation of the OS so it could run at high memory on any size system with at least 16K of RAM. I met with him the morning after he figured out how to do this and he was floating." [5]

THE "GRASSROOTS" EFFECT

Dr. Dobbs Journal, "All-CP/M Issue!" January 1980. Copyright: Dr Dobbs (www.drdobbs.com)

With the release of CP/M version 1.3, customers responded to articles such as "Upgraded CP/M floppy disc operating system now available" published in the magazine Dr Dobbs' Journal of Computer Calisthenics and Orthodontia in late 1976 by purchasing disks at $70 per copy. According to Kildall, "In the months that followed, the nature of the computer hobbyist became apparent … CP/M gradually gained popularity through a 'grassroots' effect." [1]

A licensing deal concluded with IMSAI bestowed credibility across the industry. CP/M became accepted as a standard and was offered by most early personal computer manufacturers, including pioneers Altair, Amstrad, Kaypro, and Osborne. With a SoftCard, a Zilog Z80 microprocessor -based add-in card built by Microsoft, it also ran on the Apple II to enable popular applications such as Word Star and dBASE that were originally written for CP/M. Microsoft licensed CP/M from DRI to re-sell with the card.

In 1978 Dorothy and Gary purchased a Victorian house on Lighthouse Avenue in Pacific Grove and converted the spacious two-story residence into their company headquarters. One of their first recruits, Tom Rolander joined from Intel in 1979 and immediately set to work writing MP/M, a compatible multi-tasking version of CP/M.

By 1980 DRI employed more than 20 people and Fortune magazine reported that the company generated revenue of $3.5 million. [6] The same article noted that Microsoft earned about the same total over the prior 5 years combined, some of these sales being derived from reselling CP/M licenses. By 1982 DRI disclosed annualized sales in excess of $20 million and that "More than a million people are now using CP/M controlled systems." [7]

MEANWHILE IN SEATTLE

In 1980 Rod Brock, owner of Seattle Computer Products, had developed a system using the 8086, a powerful new 16-bit microprocessor from Intel. Impatient for CP/M-86, DRI's promised upgrade for the new chip, his programmer Tim Paterson filled the gap by writing an operating system known initially as QDOS (Quick and Dirty Operating System) and later called 86-DOS. According to Paterson "if there had been a CP/M for the 8086 microprocessor, 86-DOS would never have been developed."

"I used the 1976 CP/M Interface Guide for my description of the requirements." To help developers port their software products from the 8080 to the 8086, "I also provided some similar commands from the console," said Paterson. "So 86-DOS generally had all the same application visible elements as CP/M—the function codes, the entry, point address, part of the File Control Block layout, etc." [8] He had written his operating system to emulate the 'look-and-feel' of

CP/M.

In July 1980, IBM assigned Philip "Don" Estridge to develop a desktop computer for the mass market. To get the IBM PC, as it became known, to market as quickly as possible, he used commercially available components, including the Intel 8088 (a lower-cost version of the 8086). When an IBM procurement team visited Bill Gates in Redmond, Washington to license Microsoft's BASIC interpreter program he referred them to DRI for an operating system.

BACK IN PACIFIC GROVE

When the IBM team arrived in Pacific Grove they met with Dorothy and worked with company attorney Gervaise "Gerry" Davis to settle the terms of a non-disclosure agreement. Gary, who had flown his aircraft to Oakland to meet an important customer, returned as scheduled to discuss technical matters. The meeting ended in an impasse over financial terms. IBM wished to purchase CP/M outright, whereas DRI sought a per-copy royalty payment in order to protect its existing base of business. With some alternative approaches in mind, Kildall tried to renew the negotiations a week later but IBM did not respond.

In the meantime, Gates negotiated terms to purchase 86-DOS from Brock. He then sold a one-time, non-exclusive license to IBM, who used the designation PC DOS, but retained the right to license the product as MS-DOS to others. When Kildall discovered that the function calls of the programmer's application interface were identical to those of the CP/M Interface Guide that was copyrighted and marked "Proprietary to Digital Research" he threatened IBM with a lawsuit.

Kildall and Davis negotiated a resolution that required IBM to market CP/M-86 alongside PC DOS. However the list price differential, $40 vs. $240 for the DRI product, discouraged consumer interest in the latter. Davis says "IBM clearly betrayed the impression they gave Gary and me." [2]

AFTERMATH

DRI continued to thrive for several years. CP/M-86 paved the way for a host of new products. CP/Net allowed cheap, simple microcomputers with no local disk storage to operate as clients from a central multiprogramming server. Concurrent CP/M-86 offered a multi-tasking operating system for the IBM PC-XT. Kildall acquired Gordon Eubanks' Compiler Systems Inc. for CBASIC and appointed him to head a language division. Both of these programs continue in daily use worldwide embedded in OS 4690, IBM's operating system for point-of-sale terminals. The company also introduced operating systems with windowing capability and menu-driven user interfaces years before Apple and Microsoft.

In other pursuits, Kildall founded KnowledgeSet with Tom Rolander where they created the first CD-ROM encyclopedia for Grolier. Brian Halla, Intel's technical liaison to DRI, recalls that he "showed me this VAX 11/780 that he had running in his basement and he was so proud of it and he said, 'I figured out a way to have a computer generate animation,' and he said, 'Watch this. And he runs a demo of a Coke bottle that starts real slowly and starts spinning and so as maybe several months went by, he lost interest in this and he sold his setup to a little company called Pixar.'" [9]

At its peak DRI employed over 500 people and opened operations in Asia and Europe. However by the mid-1980s, in the struggle with the juggernaut created by the combined efforts of IBM and Microsoft, DRI had lost the basis of its operating systems business. Gordon Eubanks recalls that "It became clear to me that Digital Research did not have the will to win and they were losing opportunities. So I went off and did my own thing." [10]

Dispirited, Kildall, who never enjoyed the responsibility of managing a large company or displayed the business acumen of Gates, and the other investors sold the company to Novell Inc. of Provo Utah in 1991. Ultimately Novell closed the California operation and in 1996 disposed of the assets to Caldera, Inc., which used DRI intellectual property assets to prevail in a lawsuit against Microsoft. [11]

After leaving DRI, Kildall continued to innovate. He moved to Austin, Texas where he founded Prometheus Light and Sound to explore wireless home networking technology and participated in charitable work for pediatric AIDS.

Gary Kildall died at age 52 following an accident in Monterey in 1994. His ashes were buried in Seattle, the hometown that he shared with Bill Gates.

THE LEGACY OF GARY KILDALL

In 1995, the Software and Information Industry Association presented a posthumous Lifetime Achievement Award to Gary Kildall citing eight significant areas in which he contributed to the microcomputer industry.

Despite these widely recognized technical accomplishments, his legacy remains mired in a tangle of myths and conspiracy theories. The most persistent being driven by a 1982 comment attributed to Bill Gates and published in the London Times newspaper that "Gary was out flying when IBM came to visit and that's why they did not get the contract." [2]

The former editor of the Times, Harold Evans atoned for that story in a PBS documentary and his book They Made America: Two Centuries of Innovators from the Steam Engine to the Search Engine. The subtitle of the chapter on Kildall, "He saw the future and made it work. He was the true founder of the personal computer revolution and the father of PC software," offers a sympathetic telling of the life and times of the brilliant and flawed genius who helped give birth to the PC operating system 40 years ago this year.

IEEE Milestone plaque installed outside 801 Lighthouse Avenue, Pacific Grove, CA

On April 25, 2014, the Institute of Electrical and Electronic Engineering "The world's largest professional association for the advancement of technology" will install a bronze IEEE Milestone in Electrical Engineering and Computing plaque outside the former DRI headquarters at 801 Lighthouse Avenue, Pacific Grove, CA. The Milestone program honors important events in electrical engineering and computing. Achievements such Thomas Edison's electric light bulb, Marconi's wireless communications, and Bell Labs first transistor are recognized with a plaque in an appropriate location. The citation reads:

Dr. Gary A. Kildall demonstrated the first working prototype of CP/M (Control Program for Microcomputers) in Pacific Grove in 1974. Together with his invention of the BIOS (Basic Input Output System), Kildall's operating system allowed a microprocessor-based computer to communicate with a disk drive storage unit and provided an important foundation for the personal computer revolution.

ACKNOWLEDGEMENTS AND REFERENCES

I would like to thank all those who have contributed information and background to this article, especially to Tom Rolander, John Wharton, and Herb Johnson who maintains a wealth of information on CP/M and the history of DRI on his website at: www.retrotechnology.com/dri/index.html

Aug. 31, 1981 - NY Times - "VENTURE CAPITALISTS' NEW ROLE" by Kenneth B. Noble

Source : [HN01BT][GDrive]

Last year T.A. Associates, a venture capital firm, sensed a ready market in gene-splicing technology. But combing the field for a likely prospect, the firm found no candidate worth the investment. So T.A. Associates formed its own company by bringing together leading scientists in the field.

The result was Immunogen, a concern headed by Dr. Baruj Benacerraf, a Nobel laureate, and scientists from Harvard, M.I.T., Yale and leading research laboratories.

The evolution of Immunogen from a concept to a functioning company illustrates how venture capitalists are increasingly acting as trailblazers in starting and building unseasoned enterprises, rather than waiting for entrepreneurs to come along seeking backing.

"Back in the 1970's, venture capitalists were more or less in the driver's seat. When we offered money to a company, few questions were asked," said C. Kevin Landry, a partner with T A. Associates, based in Boston. "Now, there's a lot more venture capital money around, and we can't wait for these things to fall into our lap. You have to make your own opportunities." Developing a Management Team

The new genetic engineering company started by T.A. Associates plans to develop a line of therapeutic drugs to fight cancer and other diseases, although the scientific techniques involved in producing the necessary substances remain largely untested. Meanwhile, T.A. Associates, with its venture capital partner, the Inco Securities Corporation, is busy building a management team to sell Immunogen's products - if and when the time comes.

T.A. Associates' skill in developing lucrative positions in such risky embryonic fields as genetic engineering and microelectronics has made it one of the most successful venture capital firms in the country.

In the past decade, T.A. Associates' return on its investments have averaged 30 percent to 40 percent. And the amount of capital available has grown from $5 million in 1969, when the firm was founded, to more than $125 million, ranking it first among independent venture capitalists, according to Venture, a trade magazine.

As Mr. Landry sees it, the key to successful venture capitalism is a keen sense of where new industries are forming and the ability to seek out companies in the forefront. Although the odds against finding a winner are high - nationally an estimated half of all such initial investments are eventually written off as tax losses - the returns can also be startlingly high. The Biogen Challenge

Three years ago, for example, T.A. Associates formed Biogen S.A. to exploit the commercial potential of advanced microbiology, principally DNA recombinant technology and advanced mutational technology. The development of Biogen presented even greater obstacles than most new companies, a T.A. Associates spokesman said, because many of the leading scientists in molecular biology lived and worked in Europe. The solution was to base the new company in Geneva and to build laboratories there as well as in Cambridge, Mass.

The strategy paid off: T.A. Associates and Inco, its venture capital partner, have seen the worth of Biogen, in which their initial investment was $150,000, swell to more than $9 million today.

Another crucial factor in successful venture capital investing is the ability to move with speed and decisiveness, industry experts say. Mr. Landry, for example, took only 48 hours to commit $1.8 million for 37 percent of Artificial Intelligence, a software firm based in Waltham, Mass. "It's important to be able to make a quick decision on a good deal before someone else stumbles across it," Mr. Landry said.

T.A. Associates has also apparently scored another timely success with one of its most recent investments, Digital Research. This month it was announced that the small California-based manufacturer of computer software was chosen as a key subcontractor for the International Business Machines Corporation's new personal computer system. Searching for Growing Concern

T.A. Associates' search for an entry into the small but flourishing microcomputer software market started last October. "We wanted to find a company in the microcomputer industry with sales in the $1 million-to-$2 million range, but who in two or three years would be pulling in $100 million," said Jacqueline Morby, a vice president at T.A. Associates, who supervised the firm's entry into this field.

"I started simply by browsing through computer trade magazines and paying attention to the largest ads - I said to myself, this must be more than just a garage type operation if it could afford to place a $4,000 ad in a magazine," Mrs. Morby said.

From there, she winnowed the field of investment candidates by calling them up and questioning them about their companies. After several weeks of research, Mrs. Morby narrowed her choices to three companies that might be potential investments for a venture capitalist.

Back then, Digital Research, the creation of Gary Kildall, 39 years old, a microcomputer software expert, was still a small producer. Although the company had penetrated an impressive share of its market - more than 300 companies were already using its operating system - most of its management decisions were handled by a small group of employees trained primarily in computer science.

Mrs. Morby said that Dr. Kildall designed "the most beautiful market strategy for a company that I'd ever seen. But like most entrepreneurs, he thought that all a venture provided was money - and we had to convince them that we had more to offer than that." Digital's 'Big Decision'

As Mrs. Morby saw it, Digital Research represented an ideal opportunity for T.A. Associates' investor group to become partners in a company that was a market leader in a completely new industry that had taken shape in the last two years.

"To become partners with a venture capitalist was a big decision for them - Dr. Kildall had a beautiful little company; he had to decide whether to remain private or to take on partners, possibly go public and become an industry leader - a household name like Apple - which is possible,"

Sept. 15, 1981 - NY Times - "DIGITAL RESOURCES DRIVEN BY SUCCESS INTO MAJOR CHANGES"

COMPANY NEWS

Digital Resources Driven by Success Into Major Changes

Special to The New York Times

PACIFIC GROVE, Calif. — When Gary Kildall inspects his company's production floor and shipping dock, he walks through a kitchen, out to a patio where the company cat is sunning itself and into a former carriage house.

There, Digital Research Inc. stockpiles its product — magnetic disks that contain software that International Business Machines has selected to operate its new personal computer.

From headquarters in a yellow Victorian house in this quiet seaside village 125 miles south of San Francisco, Digital Research and its president, Mr. Kildall, function in a casual manner that belies the concern's leading position in the fast-paced microcomputer industry.

Changing Structure

But now, to cope with increased competition and larger contracts, such as that with I.B.M., Digital Research must change. It is formalizing its management structure, accepting venture-capital financing, altering its pricing policies and even planning to expand into a 16,000-square-foot modern office building, with a view of the ocean, of course.

All this business, quite frankly, is more than Mr. Kildall cares to deal with. "Basically I am a gadget-oriented person," the jeans-clad Mr. Kildall said. "I like to work with dials and knobs. I'm not a very competitive person. I'm forced into it."

Pacific Grove, a picturesque town near the artists colony of Carmel and a two-hour drive from California's Silicon Valley, seems an unlikely place for a computer concern. But there, in a small cottage near Monterey Bay, Mr. Kildall invented in the early 1970's what is now Digital Research's main product, an operating system.

Computer Traffic Policeman

Acting like a traffic policeman, an operating system is a type of software that directs a personal computer's activities. For example, if a user wants access to certain information, the operating system tells the computer how to retrieve it.

In 1973 Mr. Kildall licensed what has become the leading operating system for microcomputers. It is called CP/M, for Control Program for Microcomputers. The operating system was selected by the Xerox Corperation for its Xerox 820 office system and by I.B.M. as an option for its personal computer, set for delivery in October.

Despite his preference for the laboratory over the board room, Mr. Kildall, who holds a Ph.D. in computer science, has built his company to 50 employees in six years. For the year ended Aug. 31, the privately held concern had sales of about $6 million, and Mr. Kildall expects $10 million in revenues this fiscal year.

"They're doing terrific; they must be smiling from ear to ear with the I.B.M. contract," said Ulric Weil, an analyst with Morgan Stanley & Company.

"Within five years, I think sales will be $100 million," said Dorothy McEwan, Mr. Kildall's wife and high school sweetheart of 19 years ago. She has handled the financial and marketing aspects of the business since the two started Digital Research in a 10-foot-by-13-foot playroom at their first Pacific Grove home, a cottage a few blocks from the ocean.

But the expansion has become too much for Mrs. McEwan to supervise.

"The company grew so rapidly that we had gone from small-time to a big-time operation, and we had to have professional managers," she said.

After having venture capitalists knocking at his door for three years, Mr. Kildall recognized earlier this year that he should let them come in. Mr. Kildall said he did not need their money, but wanted their expertise so he would not need to "take chances" with business decisions.

Last month, giving up only a small share of ownership, he brought in four: T.A. Associates of Boston, Hambrecht & Quist of San Francisco, Venrock Associates of New York and Page Mills Partners of Palo Alto.

Under their counsel, Digital Research changed the structure of its sales agreements. In the past, the concern licensed its CP/M software to microcomputer makers for a one-time fee of $50,000. The simple arrangement was a bargain for manufacturers, said David Crockett, senior vice president of Dataquest Inc., a Cupertino, Calif., market research concern.

Since Sept. 1, Digital Research has required graduated payment based on the number of computers sold by the manufacturer. Details of the contract with I.B.M. were not available.

The simple arrangement bought CP/M market penetration, however. About 300 computer makers use CP/M, which means that Mr. Kildall's operating system is driving some 250,000 microcomputers, according to Digital Research. These computers range in price from $1,000 for home systems to $30,000 for small-business systems.

At least 300 companies supply more than 1,000 software packages based on CP/M. Apple Computer Inc., the No. 1 maker of personal computers, uses its own proprietary system, but users can purchase a plug-in peripheral card to adapt their Apple computers to CP/M, thus making more applications software, especially business packages, available to them.

CP/M's strongest competition may come from Unix, an operating system developed by Bell Laboratories for 16-bit microprocessors. "Unix is competition at the higher end," said Mr. Weil of Morgan Stanley.

Unix will likely be used most by universities and by the Bell System, Dataquest's Mr. Crockett said, while CP/M "will own the rest of the world."

Previously, CP/M was used in the slower, eight-bit computers. Now, Digital Research has developed CP/M-86, ordered by I.B.M., for 16-bit machines.

Digital Research plans to branch into programming languages for computers. Just last week it purchased for an undisclosed amount Compiler Systems Inc., a small southern California concern that develops languages.

"The company has a lot of potential," the soft-spoken Mr. Kildall said. "I want to let the potential loose." He also said that he expected having a larger team would allow him to spend more time where he most likes to be — at a computer terminal.

Dorothy McEwan and her husband, Gary Kildall, in front of the seaside Victorian headquarters of Digital Research Inc. in Pacific Grove, Calif.

March 27, 1983 - NY Times - "BIG I.B.M. HAS DONE IT AGAIN" by Andrew Pollack

Source : [HN01BQ][GDrive]

SEYMOUR MERRIN, owner of the Computerworks store in Westport, Conn.,couldn't wait to start carrying I.B.M.'s new personal computer in the fall of 1981. The product was destined for success, he felt, and would be a strong addition to any computer store's product line.

What Mr. Merrin didn't anticipate, however, was that the I.B.M. computer would come to dominate his sales so much that it would make him nervous. "Right now, it's the bulk of my business, overwhelmingly," said the dealer, who is trying to push Apple computers to counteract I.B.M.'s influence. "One does not want to have one vendor or one customer dominate one's business. Any dealer who is not concerned with that is out of his gourd."

So it has been with the International Business Machines Corporation's entry into the personal computer business. Everyone expected the computer giant to be successful. The mere fact that it was I.B.M., a company that has muscled others out of the way to dominate the computer industry, virtually assured it would be a leader in the personal computer business. "They don't have to be the best, they just have to be competitive," said Peter Wright, an analyst with the Gartner Group in Stamford, Conn.

Nevertheless, the speed and extent to which I.B.M. has been successful has surprised many people, including I.B.M. itself. That is especially so since success was achieved with an unspectacular machine - albeit a well-designed one - made of off-the-shelf parts supplied by others.

Now, after 18 months in the market, I.B.M. has caught up to longtime leaders Apple Computer Inc. and the Tandy Corporation (makers of Radio Shack computers), and most market researchers expect I.B.M. to surge ahead of everyone this year or the next. Analysts estimate that I.B.M. sold 175,000 to 200,000 computers in 1982, its first full year on the market, and will sell at least 400,000 to 500,000 this year, helped by I.B.M.'s expansion to the overseas market and by a new, more powerful version of its personal computer introduced late last month. The company is also planning additional products, including a home computer selling for under $1,000 - code-named the Peanut - that is expected to be introduced by the end of the year. But I.B.M.'s importance in the industry is greater than its current market share of roughly 20 percent would indicate. Indeed, to some extent, I.B.M.'s role in the personal computer world is beginning to resemble its central role in the mainframe computer business, in which I.B.M. is the sun around which everything else revolves. The I.B.M. personal computer has become a de facto standard for personal computers in its price range of $2,500 to $5,000. Virtually every software company is giving first priority to writing programs for the I.B.M. machine. And more than 20 companies have already introduced I.B.M. "clones" - computers that are interchangeable or almost interchangeable with the I.B.M. computer, allowing the computers to use software written for the I.B.M. machine and to be sold to I.B.M.'s vast and continuously growing customer base. Indeed, as happened first with the Apple II, an entire subindustry has sprung up to supply parts, accessories and advice for the I.B.M. personal computer. Two of the top four computer magazines in terms of advertising pages in February were exclusively devoted to the I.B.M. computer, according to Adtrak Inc., an advertising tracking service in Mountainview, Calif.

The emergence of I.B.M. will hasten a shakeout that is inevitable in an industry with more than 100 suppliers. Nevertheless, Apple still remains strong. And some other potential big hitters are coming into the market, most notably the American Telephone and Telegraph Company's American Bell unit.

But just as important as its effect on the industry is the effect of the personal computer on I.B.M. itself. The computer will account for $1 billion to $2 billion in I.B.M. revenues this year, a tiny fraction of I.B.M.'s expected total of $35 to $40 billion.

Yet the computer is attracting increasing attention within I.B.M. as a pivotal product in its overall office automation thrust. "They're rethinking their entire strategy," said H. Donald Haback, a consultant and analyst at Freimark Blair & Company, an investment research firm.

Integrating the personal computer into I.B.M.'s overall strategy is becoming imperative. Already, the personal computer is proving so versatile that it is eating into sales of other, sometimes more expensive, I.B.M. products such as terminals, word processors and more expensive computers. "I.B.M. doesn't want the personal computer to cannibalize its other products," said the head of a large software company.

One victim already appears to be the System/23 Datamaster, a $10,000 computer introduced just two weeks before the personal computer and then all but lost in the excitement over the PC. And the potential for the PC to undermine I.B.M.'s more expensive word processor, the Displaywriter, was demonstrated this month when NBI Inc., a major word processing manufacturer, introduced an attachment for the personal computer that will turn it into an NBI word processor.

I.B.M.'s success in its new business stems largely from its success in the older computer markets. I.B.M. was expected to be successful and therefore received the retail shelf space and software support that are critical to making a product successful. Software companies have limited resources and generally concentrate on writing programs for the most popular computers.

"From the day it hit the marketplace, it was perceived by the software companies as a winner," said Mr. Merrin. "Because they perceived it as a winner, they wrote software for it." And because much software is being written, the I.B.M. computer became more and more successful, a selffulfilling prophecy. And that generated more software in a snowball effect.

I.B.M. also had a big advantage in selling personal computers to large corporations, which already use its mainframes. Such companies are capable of ordering thousands of personal computers at a shot. And rather than having each employee choose a computer individually, the data processing manager - I.B.M.'s traditional customer - is gaining a bigger role in choosing which computers to use. The safe route for data processing managers has always been to buy I.B.M.

STILL, other companies with resources and reputations almost as large as I.B.M.'s - such as Hewlett-Packard, Xerox and Digital Equipment - have not made the same impact that I.B.M. has. To be successful, I.B.M. had to avoid major blunders. It exhibited an adroit ability to move quickly and to adapt to retail marketing, a new environment for it. "I think they did nothing brilliant, but they did everything right," said Lee R. Greenhouse, assistant vice president for personal computer services at E.F. Hutton & Company.

I.B.M. decided to enter the personal computer business in the summer of 1980, when then-chairman Frank T. Cary gave the go-ahead, according to sources close to I.B.M. The company did not want to lose its chance for leadership in the microcomputer business in the same way it had let the Digital Equipment Corporation get the lead on it in minicomputers years earlier. Moreover, personal computers were starting to appear on the desks of its corporate customers. Some I.B.M. officials referred to the personal computer as the "logo machine.

"I.B.M. didn't want to sell mainframes to a large company where four out of five managers had an Apple on his desk," said Sanford J. Garrett, an analyst at Paine Webber Mitchell Hutchins.

The assignment was given to a group in Boca Raton, Fla., which received an unusual amount of freedom from I.B.M. bureaucratic procedures and past practices. One year later, the machine, aptly named the Personal Computer, or PC for short, was introduced.

One departure from past practice was to rely on outsiders for parts and software. The heart of the computer was Intel Corporation's 8088 microprocessor, which was capable of handling 16 bits, or units, of information at a time, compared to the eight bits of information handled by most existing computers. That made the I.B.M. computer capable of handling more complex programs than earlier computers. Another nice but not spectacularly new feature was a keyboard that was detached from the screen and had plenty of keys for special functions.

I.B.M. also relied on outside companies to supply software for the machine, such as word processing and financial modeling packages. It used an operating system - the program that acts as a computer's traffic cop - from the Microsoft Corporation of Bellevue, Wash. Use of a publicly available operating system encouraged more software companies to write programs for the I.B.M. personal computer, yet also made it easier for other manufacturers to make computers compatible with the I.B.M. machine.

The operations were conducted in great secrecy and relations between I.B.M. and its young computer programming whizzes were at first somewhat awkward. "If you haven't seen an I.B.M. nondisclosure agreement before, you wouldn't sign it," said Gary Kildall, chairman of Digital Research Inc., a software company whose CP/M-86 operating system is offered as an option for the personal computer.

I.B.M. also slowly and deliberately recruited the cream of Apple's dealers. Now there are 770 separate outlets selling the machine in the United States and Canada. The limited distribution at first meant a bonanza for those stores with the computer and it meant that in virtually every store, the I.B.M. machine became the best-selling line. In Computerland stores, a nationwide chain, only the Apple and the Osborne machines have at times sold in as high a volume as the I.B.M., said Edward E. Faber, president.

I.B.M. has also been careful to avoid marketing the product through too many channels in an attempt to prevent discounting. Apple dealers often complained they spent time with customers convincing them to buy a computer only to find the customer actually make the purchase from a discount store like New York's 47th Street Photo.

Dealers are starting to face increasingly stiff competition from another quarter, however. I.B.M.'s own sales force is becoming more aggressive in selling the computers and it was recently authorized to offer greater discounts to large accounts. That largely reflects the changing view within I.B.M. of the importance of the computer as the potential future workstation that may one day be on every office worker's desk.

I.B.M. might make the personal computer its universal terminal. The same basic unit can be stamped out and then modified at the end to act as either a terminal, a computer, or a word processor. "It will give I.B.M. incredible economies in manufacturing," said Frank R. Gens of the Yankee Group, a telecommunications consulting firm.

I.B.M. has already introduced options that allow the personal computer to play the part of a computer terminal and retrieve data from I.B.M. mainframe computers in large corporations. It recently introduced an option that would turn its terminals into personal computers. Since there are an estimated 1.5 million terminals in use, conversion of a fraction of them to personal computers could represent a significant addition to the personal computer base.

I.B.M. is also pushing into new markets, such as the home. An inexpensive computer, code-named "Peanut," is expected to be introduced before the end of the year. It is expected the machine would sell for less than $1,000, come with 64 K bytes, or more than 64,000 typed characters of memory, and would be at least partly compatible with the existing personal computer. It would compete in the upper end of the home market against machines such as the Apple IIe, the Commodore 64 and Atari 1200.

I.B.M.'s presence is hurting other companies but is not yet killing them because the overall market is growing at a rapid rate. In addition, technology is changing quickly and there are many niches for companies to position themselves around I.B.M.

The introduction of the I.B.M. machine virtually choked off sales of the Apple III, the Apple product most directly competitive. But Apple's main machine, the Apple IIe continues to sell well. Its new machine, the Lisa, is priced somewhat higher and might compete effectively by offering features not yet available on the I.B.M. computer. Tandy, which owns and franchises the Radio Shack chain, has an extremely broad line, from handheld devices to powerful desktop machines. Because it is mainly a retailer, it also has some flexibility to market products made by others.

Companies like Texas Instruments and Commodore have strength at the very low end, with products selling for a few hundred dollars or less, an area I.B.M. is not likely to invade immediately.

Meanwhile, other giants, such as the Digital Equipment Corporation, Wang and NCR are only now starting to enter the 16-bit computer market and should diminish I.B.M.'s dominance of that segment. A.T.& T.'s American Bell subsidiary is also planning an assault on the market. And the Japanese companies, which have made a weak showing so far, are expected to get stronger. I.B.M.'S LUCRATIVE COATTAILS

As I.B.M. has swept to the forefront of the personal computer business, an entire subindustry has evolved and managed to profit from the product, either by selling directly to I.B.M. or to the market, or from receiving I.B.M.'s endorsement.

Among the most obvious suppliers to profit are the Intel Corporation, which supplies the microprocessor to I.B.M., the Tandon Corporation, which has made most of the disk drives and the Microsoft Corporation, which makes the main operating system.

SCI Systems Inc. of Huntsville, Ala. is known to assemble the electronic circuit boards that are the guts of the I.B.M. personal computer. The company, traded over the counter, experienced a 52 percent revenue increase, to $90 million, in the year ended June 30, 1982, and analysts expect revenue to double in the current year. While the company would not comment, its 10K report shows that I.B.M. accounted for 41.4 percent of its revenues in fiscal year 1982, up from 18.7 percent in 1981.

Another potential market is in manufacturing computers that are compatible with the I.B.M. computer, meaning they can use software written for the P.C. Many industry observers think the Compaq Computer Corporation of Houston, which makes a portable compatible computer, is poised for meteoric growth.

Numerous other companies supply either software for the computer or hardware accessories such as disk drives, video displays, game paddles and extra memory. Hundreds of software products and hardware accessories have flooded the market.

The Quadram Corporation of Norcross, Ga., makes 20 different accessories. Its most popular product, the Quadboard, includes additional memory, a clock

and calendar and communications ports for $600. Founded in 1981, Quadram was purchased by the Intelligent Systems Corporation in December 1982 in a stock deal valued at $35 million.

Living on the edges of I.B.M.'s business can be precarious, however. When a business gets too large, I.B.M. can reach out and recapture it. Recently I.B.M. introduced its own hard disk drive, color monitor and extra memory, cutting into the sales of independent companies that were supplying those products. It also reduced prices for its personal computer by about 15 percent, potentially hurting the compatible computer manufacturers.

EXPLODING MYTHS

These stories provide great insights into the history of IT companies. Sometimes they serve to explode long-stand-

ing industry myths. For example, many in the IT industry have heard the story that Gary Kildall, the founder of Digital Research, Inc., blew off a meeting with “the suits” from IBM regarding licensing the CP/M operating system to go gal- livanting in his private airplane. Supposedly the frustrated IBM folks turned to Microsoft’s MS-DOS operating system for their PC, and DRI missed out on the greatest opportunity in the software industry.

Claims and counter-claims about this story have floated about for years. But Curt Geske was there. In his story “DRI and IBM—First Meeting,” Geske tells us the meeting was a rather mundane affair between Dorothy Kildall, who ran the business end of things, and IBM lawyers over the wording of a nondisclosure agreement. IBM made it known that Micro- soft already had a contract to do the work and expected DRI

to supply them with the full source code for CP/M, which DRI was understandably reluctant to do. DRI and IBM did eventually reach an agreement for IBM to distribute CP/M, but as recounted in Steve Maysonave’s videotaped story, the agreement was structured in a way that gave all the advantage to Microsoft. The outcome was consistent with the legend, but it hinged on the intricacies of contract negotiations rather than on Gary’s preference for flying over attending meetings

July 14, 1994 - The Seattle Times - "A Career Spent in Gates' Shadow -- Computer Pioneer Dies at 52"

Source : [HN01AM][GDrive]

Seattle native and software pioneer Gary Kildall, who died Monday at age 52, never let on publicly how he felt about losing dominance of the personal computer industry to hometown rival Bill Gates.

But in "Computer Connections," his privately circulated memoir, Mr. Kildall is blunt:

"I have grown up in the industry with Gates. He is divisive. He is manipulative. He is a user. He has taken much from me and the industry."

It's not the first time the Microsoft billionaire - who built a software empire on BASIC, a computer language invented at Dartmouth; MS-DOS, a program he purchased, and Windows, modeled after Apple Computer's Macintosh - has been called predatory. But Mr. Kildall, an easygoing type who co-hosted a public-TV show on computers called "Computer Chronicles," previously had shied from pointing the finger. Gates was unavailable for comment. A Microsoft spokeswoman said Gates "regrets Gary passed away at such a young age, and it's a loss to the industry." But, she said, "no one can deny the size and strength of the personal-computer industry that has been made possible by MS-DOS and Intel technologies becoming the standard."

Mr. Kildall, who was en route to Seattle to visit relatives, died in a Monterey, Calif., hospital. The cause of death has not been determined. A press release issued by the county coroner said Mr. Kildall was injured late Friday at a Monterey restaurant but refused treatment.

Early Saturday, an ambulance was summoned to his home, and Mr. Kildall was taken to a hospital, then released. He was readmitted Sunday and stayed in the hospital until his death.

A service will be held in Seattle on Tuesday.

In his book-length memoir, Mr. Kildall acknowledged his sentiments about Gates are "sour grapes" but he defends his version of events as "the whole truth."

Associates are trying to have the memoir, which was shown to The Seattle Times, published by a trade press. Mr. Kildall spent two years writing it and did a limited printing for family and friends last fall.

Wrote one of the first systems

Twenty years ago, Mr. Kildall wrote CP/M, the first popular operating system for desktop computers. Called by some the father of personal computing for that contribution, Mr. Kildall became better known for something he didn't do.

In 1980, IBM needed an operating system for its personal computer project and was directed by Gates to Mr. Kildall's Digital Research Inc. in Pacific Grove, Calif. To run applications, a computer needs an operating system. IBM wanted to ship one with each of its new PCs.

In a frequently told story with numerous conflicting versions, IBM visited Digital Research, only to be rebuffed when Mr. Kildall's wife at that time, Dorothy McEwen, balked at signing a form limiting disclosure of the relationship between the companies.

Gates later told interviewers "Gary went flying" at the pivotal historical moment. But Mr. Kildall wrote that he returned from flying his Piper Turbo Arrow to a business appointment in the afternoon, signed the agreement and began negotiating a deal with IBM.

IBM wanted to purchase CP/M-86 outright for $250,000, but Mr. Kildall held out for the standard royalty of $10 a copy.

Mr. Kildall's version has never been confirmed. Jack Sams, an IBM program manager at the time, said Mr. Kildall was missing from most of the meeting but "might have been there at the time they signed the letter (nondisclosure agreement)." Mr. Kildall's ex-wife McEwen declined comment. Gerry Davis, his attorney at the time, did not return phone calls.

Tom Rolander, a Digital Research executive then, said he was with Mr. Kildall on the San Jose trip and at the meeting. He declined to give details but said, "a careful analysis of the whole relationship will indicate how ruthless IBM and Gates were, and how innocent Gary was." Mr. Kildall "was not a Gates-type person. He was an inventor of technology, not a businessman."

Gates steps into breach

When IBM returned without a deal, Gates purchased an operating system from Seattle Computer Products called QDOS, for Quick and Dirty Operating System, for use on the IBM PC. After renaming the program MS-DOS, Microsoft licensed it to makers of IBM PC "clones," making it by the mid-1980s the prevailing operating system for personal computers.

When Mr. Kildall, who had shown IBM his system, saw an early copy of DOS, he was incensed over similarities between the two. At a meeting with IBM, he agreed not to sue for copyright infringement if IBM marketed his program. IBM later priced CP/M at $240 but charged only $40 for DOS.

"The pricing difference set by IBM killed CP/M-86," Mr. Kildall wrote in the book. IBM's Sams acknowledged the price difference but said it reflected Mr. Kildall's higher price to IBM, which he recalls as $100 a unit.

Mr. Kildall, who knew Gates from the latter's early computing days at C-Cubed, a University District computer center, made millions from CP/M. But he was destined to be cast as the guy who lost the big one.

Mr. Kildall's and Gates' paths crossed often. In 1977 the two discussed merging their companies while Gates tried to decide where to move Microsoft, then in Albuquerque.

Mr. Kildall later offered to sell Digital Research for $26 million to Gates, who told him the company was worth no more than $10 million. In 1991, Digital Research was sold for $120 million to Novell.

Teaching, then work at Intel

While studying at the UW in the late 1960s, Mr. Kildall had entered the Navy. When given the choice between serving in Vietnam or teaching at the Naval Postgraduate School in California, he chose the latter. In 1973 he went to work for Intel, which today supplies chips for 80 percent of the world's personal computers. In 1976 he founded Intergalactic Digital Research. He soon shortened the name.

Mr. Kildall licensed CP/M to IMSAI, an early personal-computer manufacturer. By 1980 it had become the industry standard.

In an appendix, Mr. Kildall reprints copies of code for CP/M and DOS showing, he maintains, that the first 26 lines, or calls, are identical. Seattleite Tim Paterson, author of QDOS, has acknowledged that it was modeled after CP/M but denies it was a direct copy. In his book, Mr. Kildall calls it "plain and simple theft."

Mr. Kildall wrote he was advised by Davis, his attorney, not to sue. At the time, the software community widely imitated one another's work. Later, suing over "look and feel" and copyright or patent infringement became a means of protecting what became intellectual property potentially worth billions.

Mr. Kildall stayed with Digital Research through the 1980s and worked on a variety of ventures. He was residing in Austin, Texas, at the time of his death.

"We all thought Gary was a genius," said his sister, Patricia Guberlet of Seattle. "He was a genuinely likable person" who never received recognition tantamount to his contribution, she added.

"He paved the way for everybody," said a cousin, Tom Kildall, a Seattle marine-insurance broker. "When I talked to him about it (the lost IBM deal), it was like, `That's the way it goes.' All it would have gotten him was more money, and he wasn't poor."

Gary attended high school at Lincoln in Wallingford but graduated from Queen Anne High in 1960, his sister said. He enrolled at the UW in 1963 and earned a doctorate in computer science.

Mr. Kildall is survived by his mother, Emma, of Seattle; his sister; an uncle, Bob, of Seattle; a daughter, Kristin, of Seattle, and son Scott of Oakland. Services will be held tomorrow in Monterey and 11 a.m. Tuesday in Seattle's Trinity Parish Episcopal Church at 609 Eighth Ave. Donations may be made to Make-A-Wish Foundation.

Jul 16, 1994 - The Seattle Times - "Computer Pioneer's Death Probed -- Kildall Called Possible Victim Of Homicide" by Peyton Whitely

Source : [HN01AN][GDrive]

The death of Gary Kildall, who's been called the father of the personal computer, is being investigated by California police as a possible homicide.

Kildall, 52, a Seattle native who devised a computer-operating system known as CP/M, died Monday in Monterey, Calif., of what a coroner's report described as a traumatic head injury.

The report on the cause of death also said that Kildall suffered from chronic alcoholism, which it cited as a contributing medical condition. The coroner's report said the fatal injury may have taken place "as a result of foul play" and the incident was being turned over to the Monterey Police Department.

"We're going to investigate it as a possible homicide," said police Sgt. Frank Sollecito. "I'm not going to flat-out say it's a homicide."

Kildall was injured at the Franklin Street Bar & Grill on July 8 but refused medical treatment. He was taken to a hospital the following day and released.

But he was readmitted Sunday and died the following day.

Kildall could have died either from a blow to the head or from hitting his head as he fell, said Sollecito.

The first description of the incident at the bar, he said, was that Kildall had been in the bar between two to 20 minutes. Then witnesses "turned around, and he was on the floor," the sergeant said.

But Sollecito said stories are changing. "That version isn't going to hold up," he said.

Medical evidence of chronic alcoholism was found during the autopsy, said Sgt. Jim Smith, coroner-division commander for the Monterey County Sheriff's Department.

Kildall's CP/M was considered by IBM as a possible operating system for its new personal computers in 1980. But according to computer-age lore, IBM instead chose a competing system known as MS-DOS, buying it from another Seattle man named Bill Gates, who ran a company called Microsoft.

Kildall later wrote a private memoir that included a description of the IBM deal, entitling it "Computer Connections." In it, he told how he thought he had an agreement with IBM but the proper documents never were signed and the deal slipped away.

Gates has told his own version of the deal and of how Kildall lost it by going flying instead of attending a meeting with IBM. Numerous conflicting versions of the supposed arrangements exist.

Kildall later sold his company, Digital Research, for $120 million, and Gates went on to make billions of dollars through Microsoft.

2020 (Jan 05) - "The Death of Gary Kildall Remains a Mystery to This Date"

Posted in Bill Gates, Deception, Microsoft at 6:16 am by Dr. Roy Schestowitz

http://techrights.org/2020/01/05/history-canceled/

2020-01-05-techrights-org-history-cancelled

'He [Bill Gates] is divisive. He is manipulative. He is a user. He has taken much from me and the industry.' -Gary Kildall

Summary: Mr. Kildall reportedly “suffered a fatal heart attack,” but more recent media reports speak of a “biker bar brawl during a night out in Monterey” as the cause of death (shades of the last moments of Ian Murdock, who had been severely abused by police and then — after shocking humiliation — decided to hang himself)

THERE’s a story or two surrounding the relatively mysterious death of Gary Kildall at the age of 52. The story I heard as a young person may have changed over time (revisionism by the ‘victor’ plays a role), but Wikipedia puts it like this (at this time): “On July 8, 1994, Kildall fell at a Monterey, California, biker bar and hit his head.[26] The exact circumstances of the injury remain unclear. He had been an alcoholic in his later years.[15][27] Various sources have claimed he fell from a chair, fell down steps, or was assaulted, because he had walked into the Franklin Street Bar & Grill wearing Harley-Davidson leathers.[12] He checked in and out of the hospital twice, and died three days later at the Community Hospital of the Monterey Peninsula. An autopsy the next day did not conclusively determine a cause of death.[25][1] A CP/M Usenet FAQ says he was concussed from the fall and died of a heart attack; the connection between the two are unclear.[28] He is buried in Evergreen Washelli Memorial Park in north Seattle.”

Wikipedia cites several articles from sites that are funded by Bill Gates, for example the Seattle Times. They’re not likely to be objective.

“No matter if people retire early (unhappy with the way things are going), or leave due to health circumstances, or are forced to resign, or die earlier than expected and so on… the net effect is that they have less of a role to play.”To quote an associate of ours, “I read on TR (Techrights) that Bruce Perens has been driven out of OSI. Do you have a list? Guido, RMS, Linus, probably many others.”

“Perens himself left,” I responded, “after seeing the OSI doing bad things.”

No matter if people retire early (unhappy with the way things are going), or leave due to health circumstances, or are forced to resign, or die earlier than expected and so on… the net effect is that they have less of a role to play. Even Linus Torvalds is nowhere as active as he used to be; he mostly participates in announcements.

For the sake of documenting the fate of Mr. Kildall, here’s a copy of an article by Clive Akass of Personal Computer World that is no longer online (but exists on the Wayback Machine):

The birth of the IBM PC was also the making of Bill Gates, thanks to a door-step farce that has become an industry legend.

IBM at the time had dominated the industry for a quarter-century, though it had been late getting into digital computers, and even later getting into what were then called microcomputers, which it tried to pretend were not a threat to its mainframe business. By the late 1980s ‘micros’ (as in Microsoft) could not be ignored, and IBM set up a team to design one

The obvious person to provide the software was Gary Kildall, head of a company called Digital Research, who had written CP/M – the operating system used on almost all micros.

Legend has it that two suits from IBM called by appointment at Kildall’s home, but he was off flying and had left his wife Dorothy to do the talking. She baulked at signing a non-disclosure agreement and showed them the door

So they turned instead to a fledgling company run by a 24-year-old college dropout whose name was Bill Gates. Microsoft did not even have an operating system and promptly bought one called QDos, virtually a CP/M clone, for $50,000 from a Seattle engineer called Tim Patterson.

The legend is essentially true, though what really hassled Dorothy Kildall when IBM showed up was the fact that she was preparing to go on holiday the next day, according to former Symantec chief executive Gordon Eubanks, who knew everyone involved. No-one at the time knew that the IBM computer was going to become the industry’s major standard platform.

And the real reason Kildall did not get the contract was that he was simply too laid back to be a good businessman, Eubanks told me in 1996. “Gary could have owned this business [ie, computing] if he had made the right strategic decisions… He did not care that much. Dorothy ran the business and he ran the technical side, and they did not get on.”

It was Gates who had the vision. “Bill was extremely focused and driven,” Eubanks recalled.

Microsoft tweaked QDos a little and called it MS-Dos. It ended up running in nine out of 10 of the world’s PCs, and traces of it can still be found buried in Windows XP.

CP/M lingered on for a few years and Novell bought Digital Research in 1991. Kildall died in 1994 at the age of 52 from injuries received in a biker bar brawl during a night out in Monterey, California.

Kildall was one of the founding fathers of desktop computing, but he seems destined to go down in history as the man who gave Bill Gates the world.

The narrative of a brawl is partly disputed here:

Q4: What ever happened to Digital Research and Gary Kildall?

a: (Don Kirkpatrick)

DRI was bought out by Novell and subsequently sold off to Caldera, which currently owns the copyright to all DRI software.

Personal computer pioneer Gary Kildall, who but for a single failed business deal might have enjoyed the wealth and fame of Bill Gates, died July 11, 1994, in a Monterey hospital at age 52.

Kildall was taken to the hospital after suffering a concussion in a fall. Evidence indicates Kildall suffered a fatal heart attack. It is unclear if the two conditions were related.

What troubles us most is the degree to which Gates-funded sites have been rewriting the history as recently as a couple of years back (when the Wikipedia article was last edited). Money buys narrative.

[HB004V][GDrive]

You have to wonder what it was we were doing before we had all these computers in our lives. Same stuff, pretty much. Down at the auto parts store, the counterman had to get a ladder and climb way the heck up to reach some top shelf, where he'd feel around in a little box and find out that the muffler clamps were all gone. Today he uses a computer, which tells him that there are three muffler clamps sitting in that same little box on the top shelf. But he still has to get the ladder and climb up to get them, and, worse still, sometimes the computer lies, and there are no muffler clamps at all, spoiling the digital perfection of the auto parts world as we have come to know it.

What we're often looking for when we add the extra over head of building a computer into our businesses and our lives is certainty. We want something to believe in, something that will take from our shoulders the burden of knowing when to reorder muffler clamps. In the twelfth century, before there even were muffler clamps, such certainty came in the form of a belief in God, made tangible through the building of cathedrals—places where God could be accessed. For lots of us today, the belief is more in the sanctity of those digital zeros and ones, and our cathedral is the personal computer. In a way, we're replacing God with Bill Gates.

Uh-oh.

The problem, of course, is with those zeros and ones. Yes or no, right or wrong, is what those digital bits seem to signify, looking so clean and unconflicted that we forget for a moment about that time in the eighth grade when Miss Schwerko humiliated us all with a true-false test. The truth is, that for all the apparent precision of computers, and despite the fact that our mothers andTom Peters would still like to believe that perfection is attainable in this life, computer and software companies are still remarkably imprecise places, and their products reflect it.

And why shouldn't they, since we're still at the fumbling stage, where good and bad developments seem to happen at random. Look at Intel, for example. Up to this point in the story, Intel comes off pretty much as high-tech heaven on earth. As the semiconductor company that most directly begat the personal computer business, Intel invented the microprocessor and memory technologies used in PCs and acted as an example of how a high-tech company should be organized and managed.

But that doesn't mean that Bob Noyce's crew didn't screw up occasionally.

There was a time in the early 1980s when Intel suffered terrible quality problems. It was building microprocessors and other parts by the millions and by the millions these parts tested bad. The problem was caused by dust, the major enemy of computer chip makers. When your business relies on printing metal lic traces that are only a millionth of an inch wide, having adust mote ten times that size come rolling across a silicon wafer means that some traces won't be printed correctly and some parts won't work at all.A few bad parts are to be expected, since there are dozens, sometimes hundreds, printed on a single wafer, which is later cut into individual components. But Intel was suddenly getting as many bad parts as good, and that was bad for business.

Semiconductor companies fight dust by building their components in expensive clean rooms, where technicians wear surgical masks, paper booties, rubber gloves, and special suits and where the air is specially filtered. Intel had plenty of clean rooms, but it still had a big dust problem, so the engineers cleverly decided that the wafers were probably dusty before they ever arrived at Intel. **The wafers were made in the East by Monsanto.**

Suddenly it was Monsanto's dust problem.

Monsanto engineers spent months and millions trying to eliminate every last speck of dust from their silicon wafer production facility in South Carolina. They made what they thought was terrific progress, too, though it didn't show in Intel's production yields, which were still terrible. The funny thing was that Monsanto's other customers weren't complaining. IBM, for example, wasn't complaining, and IBM was a very picky customer, always asking for wafers that were extra-big or extra small or triangular instead of round. IBM was having no dust problems.

If Monsanto was clean and Intel was clean, the only remain ing possibility was that the wafers somehow got dusty on their trip between the two companies, so the Monsanto engineers hired a private investigator to tail the next shipment of wafers to Intel. Their private eye uncovered an Intel shipping clerk who was opening incoming boxes of super-clean silicon wafers and then counting out the wafers by hand into piles on a super-unclean desktop, just to make sure that Bob Noyce was getting every silicon wafer he was paying for.

The point of this story goes far beyond the undeification of Intel to a fundamental characteristic of most high-tech businesses. There is a business axiom that management gurus spout and that big-shot industrialists repeat to themselves as a mantra if they want to sleep well at night. The axiom says that when a business grows past $1 billion in annual sales, it becomes too large for any one individual to have a significant impact. Alas, this is not true when it's a $1 billion high-tech business, where too often the critical path goes right through the head of one particular programmer or engineer or even through the head of a well-meaning clerk down in the shipping department. Remember that Intel was already a $1 billion company when it was brought to its knees by desk dust.

The reason that there are so many points at which a chip, a computer, or a program is dependent on just one person is that the companies lack depth. Like any other new industry, this is one staffed mainly by pioneers, who are, by definition, a small minority. People in critical positions in these organizations don't usually have backup, so when they make a mistake, the whole company makes a mistake.

My estimate, in fact, is that there are only about twenty-five real people in the entire personal computer industry—this ship ping clerk at Intel and around twenty-four others. Sure, Apple Computer has 10,000 workers, or says it does, and IBM claims nearly 400,000 workers worldwide, but has to be lying. Those workers must be temps or maybe androids because I keep running into the same two dozen people at every company I visit.

Maybe it's a tax dodge. Finish this book and you'll see; the companies keep changing, but the names are always the same. Intel begat the microprocessor and the dynamic random access memory chip, which made possible MITS, the first of many per sonal computer companies with a stupid name. And MITS, in turn, made possible Microsoft,, because computer hardware must exist, or at least be claimed to exist, before programmers can

even envision software for it. Just as cave dwellers didn't squat with their flint tools chipping out parking brake assemblies for 1967 Buicks, so programmers don't write software that has no computer upon which to run. Hardware nearly always leads soft ware, enabling new development, which is why Bill Gates's con version from minicomputers to microcomputers did not come (could not come) until 1974, when he was a sophomore at Harvard University and the appearance of the MITS Altair 8800 computer made personal computer software finally possible.

Like the Buddha, Gates's enlightenment came in a flash. Walking across Harvard Yard while Paul Allen waved in his face the January 1975 issue of Popular Electronics announcing the Altair 8800 microcomputer from MITS, they both saw instantly that there would really be a personal computer industry and that the industry would need programming languages. Although there were no microcomputer software companies yet, 19-year-old Bill's first concern was that they were already too late. "We realized that the revolution might happen without us," Gates said. "After we saw that article, there was no question of where our life would focus."

"Our lifel" What the heck does Gates mean here—that he and Paul Allen were joined at the frontal lobe, sharing a single life, a single set of experiences? In those days, the answer was "yes." Drawn together by the idea of starting a pioneering soft ware company and each convinced that he couldn't succeed alone, they committed to sharing a single life—a life unlike that of most other PC pioneers because it was devoted as much to doing business as to doing technology.

Gates was a businessman from the start; otherwise, why would he have been worried about being passed by? There was plenty of room for high-level computer languages to be developed for the fledgling platforms, but there was only room for one first high-level language. Anyone could participate in a movement, but only those with the right timing could control it. Gates knew that the first language—the one resold by MITS, maker of the Altair—would become the standard for the whole industry. Those who seek to establish such de facto standards in any industry do so for business reasons.

"This is a very personal business, but success comes from appealing to groups," Gates says. "Money is made by setting d<_ facto standards."

The Altair was not much of a consumer product. It came typically as an unassembled $350 kit, clearly targeting only the electronic hobbyist market. There was no software for the machine, so, while it may have existed, it sure didn't compute. There wasn't even a keyboard. The only way of programming the computer at first was through entering strings of hexadecimal code by flicking a row of switches on the front panel. There was no display other than some blinking lights. The Altair was limited in its appeal to those who could solder (which eliminated most good programmers) and to those who could program in machine language (which eliminated most good solderers).

BASIC was generally recognized as the easiest programming language to learn in 1975. It automatically converted simple English-like commands to machine language, effectively removing the programming limitation and at least doubling the number of prospective Altair customers.

Since they didn't have an Altair 8800 computer (nobody did yet), **Gates and Allen wrote a program that made a PDP-10 mini computer at the Harvard Computation Center simulate the Altair's Intel 8080 microprocessor. In six weeks, they wrote a version of the BASIC programming language that would run on the phantom Altair synthesized in the minicomputer.** They hoped it would run on a real Altair equipped with at least 4096 bytes of random access memory. The first time they tried to run the language on a real microcomputer was when Paul Allen demonstrated the product to MITS founder Ed Roberts at the company's headquarters in Albuquerque. To their surprise and relief, it worked.

MITS BASIC, as it came to be called, gave substance to the microcomputer. Big computers ran BASIC. Real programs had been written in the language and were performing business, educational, and scientific functions in the real world. While the Altair was a computer of limited power, the fact that Allen and Gates were able to make a high-level language like BASIC run on the platform meant that potential users could imagine running these same sorts of applications now on a desktop rather than on a mainframe.

MITS BASIC was dramatic in its memory efficiency and made the bold move of adding commands that allowed programmers to control the computer memory directly. MITS BASIC wasn't perfect. The authors of the original BASIC, John Kemeny and Thomas Kurtz, both of Dartmouth College, were concerned that Gates and Allen's version deviated from the language they had designed and placed into the public domain a decade before. Kemeny and Kurtz might have been unimpressed, but the hobbyist world was euphoric.

I've got to point out here that for many years Kemeny was president of Dartmouth, a school that didn't accept me when I was applying to colleges. Later, toward the end of the Age of Jimmy Carter, I found myself working for Kemeny, who was then head of the presidential commission investigating the Three Mile Island nuclear accident. One day I told him how Dartmouth had rejected me, and he said, "College admissions are never per fect, though in your case I'm sure we did the right thing." After that I felt a certain affection for Bill Gates.

Gates dropped out of Harvard, Allen left his programming job at Honeywell, and both moved to New Mexico to be close to their customer, in the best Tom Peters style. Hobbyists don't move across country to maintain business relationships, but businessmen do. They camped out in the Sundowner Motel on Route 66 in a neighborhood noted for all-night coffee shops, hookers, and drug dealers.

Gates and Allen did not limit their interest to MITS. They wrote versions of BASIC for other microcomputers as they came to market, **leveraging their core technology**. The two eventually had a falling out with Ed Roberts of MITS, who claimed that he owned MITS BASIC and its derivatives; they fought and won, something that hackers rarely bothered to do. Capitalists to the bone, they railed against software piracy before it even had a name, writing whining letters to early PC publications. Gates and Allen started Microsoft with a stated mission of putting "a computer on every desk and in every home, running Microsoft software." Although it seemed ludicrous at the time, they meant it.

While Allen and Gates deliberately went about creating an industry and then controlling it, they were important exceptions to the general trend of PC entrepreneurism. Most of their eventual competitors were people who managed to be in just the right place at the right time and more or less fell into business. These people were mainly enthusiasts who at first developed computer languages and operating systems for their own use. It was worth the effort if only one person—the developer himself—used their product. Often they couldn't even imagine why anyone else would be interested.

Gary Kildall, for example, invented the first microcomputer operating system because he was tired of driving to work. In the early 1970s, Kildall taught computer science at the Naval Post graduate School in Monterey, California, where his specialty was compiler design. Compilers are software tools that take entire pro grams written in a high-level language like FORTRAN or Pascal and translate them into assembly language, which can be read directly by the computer. High-level languages are easier to learn than Assembler, so compilers allowed programs to be completed faster and with more features, although the final code was usually longer than if the program had been written directly in the internal language of the microprocessor. Compilers translate, or com pile, large sections of code into Assembler at one time, as opposed to interpreters, which translate commands one at a time.

By 1974, Intel had added the 8008 and 8080 to its family of microprocessors and had hired Gary Kildall as a consultant to write software to emulate the 8080 on a DEC time-sharing system, much as Gates and Allen would shortly do at Harvard. Since there were no microcomputers yet, Intel realized that the best way for companies to develop software for microprocessor-based devices was by using such an emulator on a larger system. Kildall's job was to write the emulator, called Interp/80, followed by a high-level language called PL/M, which was planned as a microcomputer equivalent of the XPL language developed for mainframe computers at Stanford University. Nothing so mundane (and useful by mere mortals) as BASIC for Gary Kildall, who had a Ph.D. in compiler design.

What bothered Kildall was not the difficulty of writing the software but the tedium of driving the fifty miles from his home in Pacific Grove across the Santa Cruz mountains to use the Intel minicomputer in Silicon Valley, He could have used a remote teletype terminal at home, but the terminal was incredibly slow for inputting thousands of lines of data over a phone line; driving was faster.

Or he could develop software directly on the 8080 processor, bypassing the time-sharing system completely. Not only could he avoid the long drive, but developing directly on the microprocessor would also bypass any errors in the minicomputer 8080 emulator. The only problem was that the 8080 microcomputer Gary Kildall wanted to take home didn't exist.

What did exist was the Intellec-8, an Intel product that could be used (sort of) to program an 8080 processor. The Intellec-8 had a microprocessor, some memory, and a port for attaching a Teletype 33 terminal. There was no software and no method for storing data and programs outside of main memory.

The primary difference between the Intellec-8 and a micro-computer was external data storage and the software to control it. IBM had invented a new device, called a floppy disk, to replace punched cards for its minicomputers. The disks themselves could be removed from the drive mechanism, were eight inches in diameter, and held the equivalent of thousands of pages of data. Priced at around $500, the floppy disk drive was perfect for Kildall's external storage device. Kildall, who didn't have $500, convinced Shugart Associates, a floppy disk drive maker, to give him a worn-out floppy drive used in its 10,000-hour torture test. While his friend John Torode invented a controller to link the Intellec-8 and the floppy disk drive, Kildall used the 8080 emulator on the Intel time-sharing system to develop his operating system, called CP/M, or Control Program/Monitor.

If a computer acquires a personality, it does so from its operating system. Users interact with the operating system, which interacts with the computer. The operating system controls the flow of data between a computer and its long-term storage sys tem. It also controls access to system memory and keeps those bits of data that are thrashing around the microprocessor from thrashing into each other. Operating systems usually store data in files, which have individual names and characteristics and can be called up as a program or the user requires them. Gary Kildall developed CP/M on a DEC PDP-10 minicomputer running the TOPS-10 operating system. Not surprisingly, most CP/M commands and file naming conventions look and op erate like their TOPS-10-counterparts. It wasn't pretty, but it did the job.

By the time he'd finished writing the operating system, Intel didn't want CP/M and had even lost interest in Kildall's PL/M language. **The only customers for CP/M in 1975 were a maker of intelligent terminals and Lawrence Livermore Labs, which used CP/M to monitor programs on its Octopus network.**

In 1976, Kildall was approached by Imsai, the second personal computer company with a stupid name. Imsai manufactured an early 8080-based microcomputer that competed with the Altair. In typical early microcomputer company fashion, Imsai had sold floppy disk drives to many of its customers, promising to send along an operating system eventually. With each of them now holding at least $1,000 worth of hardware that was only gathering dust, the customers wanted their operating system, and CP/M was the only operating system for Intel-based computers that was actually available.

By the time Imsai came along, Kildall and Torode had adapted CP/M to four different floppy disk controllers. There were probably 100 little companies talking about doing 8080- based computers, and neither man wanted to invest the endless hours of tedious coding required to adapt CP/M to each of these new platforms. So they split the parts of CP/M that interfaced with each new controller into a separate computer code module, called the Basic Input/Output System, or BIOS. With all the hard ware-dependent parts of CP/M concentrated in the BIOS, it be came a relatively easy job to adapt the operating system to many different Intel-based microcomputers by modifying just the BIOS. With his CP/M and invention of the BIOS, Gary Kildall defined the microcomputer. Peek into any personal computer to day, and you'll find a general-purpose operating system adapted to specific hardware through the use of a BIOS, which is now a specialized type of memory chip.

In the six years after Imsai offered the first CP/M computer, more than 500,000 CP/M computers were sold by dozens of makers. Programmers began to

write CP/M applications, relying on the operating system's features to control the keyboard, screen, and data storage. This base of applications turned CP/M into a de facto standard among microcomputer operating systems, guaranteeing its long-term success. Kildall started a company called Intergalactic Digital Research (later, just Digital Research) to sell the software in volume to computer makers and direct to users for $70 per copy. He made millions of dollars, essentially without trying.

Before he knew it, Gary Kildall had plenty of money, fast cars, a couple of airplanes, and a business that made increasing demands on his time. His success, while not unwelcome, was unexpected, which also meant that it was unplanned for. Success brings with it a whole new set of problems, as Gary Kildall discovered. You can plan for failure, but how do you plan for success?

Every entrepreneur has an objective, which, once achieved, leads to a crisis. In Gary Kildall's case, the objective—just to write CP/M, not even to sell it—was very low, so the crisis came quickly. He was a code god, a programmer who literally saw lines of code fully formed in his mind and then committed them effortlessly to the keyboard in much the same way that Mozart wrote music. He was one with the machine; what did' he need with seventy employees?

"Gary didn't give a shit about the business. He was more interested in getting laid," said Gordon Eubanks, a former student of Kildall who led development of computer languages at Digital Research. "So much went so well for so long that he couldn't imagine it would change. When it did—when change was forced upon him—Gary didn't know how to handle it."

"Gary and Dorothy [Kildall's wife and a Digital Research vice-president] had arrogance and cockiness but no passion for products. No one wanted to make the products great. Dan Bricklin [another PC software pioneer—read on] sent a document saying what should be fixed in CP/M, but it was ignored. Then I urged Gary to do a BASIC language to bundle with CP/M, but when we finally got him to do a language, he insisted on PL/i —a virtually unmarketable language."

Digital Research was slow in developing a language business to go with its operating systems. It was also slow in updating its core operating system and extending it into the new world of 16-bit microprocessors that came along after 1980. The company in those days was run like a little kingdom, ruled by Gary and Dorothy Kildall.

"In one board meeting," recalled a former Digital Research executive, "we were talking about whether to grant stock options to a woman employee. Dorothy said, 'No, she doesn't de serve options—she's not professional enough; her kids visit her at work after 5:00 p.m.' Two minutes later, Christy Kildall, their daughter, burst into the boardroom and dragged Gary off with her to the stable to ride horses, ending the meeting. Oh yeah, Dorothy knew about professionalism."

"Let's say for a minute that Eubanks was correct, and Gary Kildall didn't give a shit about the business. Who said that he had to? CP/M was his invention; Digital Research was his company. The fact that it succeeded beyond anyone's expectations did not make those earlier expectations invalid. Gary Kildall's ambition was limited, something that is not supposed to be a factor in American business. If you hope for a thousand and get a million, you are still expected to want more, but he didn't.

It's easy for authors of business books to get rankled by characters like Gary Kildall who don't take good care of the empires they have built. But in fact, there are no absolute rules of behavior for companies like Digital Research. The business world is, like computers, created entirely by people. God didn't come down and say there will be a corporation and it will have a board of directors. We made that up. Gary Kildall made up Digital Research.

Eubanks, who came to Digital Research after a naval career spent aboard submarines, hated Kildall's apparent lack of discipline, not understanding that it was just a different kind of discipline. Kildall was into programming, not business. "Programming is very much a religious experience for a lot of people," Kildall explained. "If you talk about programming to a group of programmers who use the same language, they can become almost evangelistic about the language. They form a tight-knit community, hold to certain beliefs, and follow certain rules in their programming. It's like a church with a program ming language for a bible."

Gary Kildall's bible said that writing a BASIC compiler to go with CP/M might be a shrewd business move, but it would be a step backward technically; Kildall wanted to break new ground, and a BASIC had already been done by Microsoft. "The unstated rule around Digital Research was that Microsoft did languages, while we did operating systems," Eubanks explained. "It was never stated emphatically, but I always thought that Gary assumed he had an agreement with Bill Gates about this separation and that as long as we didn't compete with Microsoft, they wouldn't compete with us."

Sure.

The Altair 8800 may have been the first microcomputer, but it was not a commercial success. The problem was that assembly took from forty to an infinite number of hours, depending on the hobbyist's mechanical ability. When the kit was done, the micro computer either worked or didn't. If it worked, the owner had a programmable computer with a BASIC interpreter, ready to run any software he felt like writing.

The first microcomputer that was a major commercial success was the Apple II. It succeeded because it was the first micro computer that looked like a consumer electronic product. You could buy the Apple from a dealer who would fix it if it broke and would give you at least a little help in learning to operate the beast. The Apple II had a floppy disk drive for data storage, did not require a separate Teletype or video terminal, and offered color graphics in addition to text. Most important, you could buy software written by others that would run on the Apple and with which a novice could do real work.

The Apple II still defines what a low-end computer is like. **Twenty-third century archaeologists excavating some ancient ComputerLand stockroom will see no significant functional difference between an Apple II of 1978 and an IBM PS/2 of 1992.** Both have processor, memory, storage, and video graphics. Sure, the PS/2 has a faster processor, more memory and storage, and higher-resolution graphics, but that only matters to us today. By the twenty-third century, both machines will seem equally primitive.

The Apple II was guided by three spirits. Steve Wozniak invented the earlier Apple I to show it off to his friends in the Homebrew Computer Club. Steve Jobs was Wozniak's younger sidekick who came up with the idea of building computers for sale and generally nagged Woz and others until the Apple II was working to his satisfaction. Mike Markkula was the semiretired Intel veteran (and one of Noyce's boys) who brought the money and status required for the other two to be taken at all seriously.

Wozniak made the Apple II a simple machine that used clever hardware tricks to get good performance at a smallish price (at least to produce—the retail price of a fully outfitted Apple II was around $3,000). **He found a way to allow the micro processor and the video display to share the same memory. His floppy disk controller, developed during a two-week period in December 1977, used less than a quarter the number of integrated circuits required by other controllers at the time.** The Apple's floppy disk controller made it clearly superior to machines appearing about the same time from Commodore and Radio Shack. More so than probably any other microcomputer, the Apple II was the invention of a single person; even Apple's original BASIC interpreter,

which was always available in read only memory, had been written by Woz.

Woz made the Apple II a color machine to prove that he could do it and so he could use the computer to play a color version of Breakout, a video game that he and Jobs had designed for Atari. Markkula, whose main contributions at Intel had been in finance, pushed development of the floppy disk drive so the computer could be used to run accounting programs and store resulting financial data for small business owners. Each man saw the Apple II as a new way of fulfilling an established need— to replace a video game for Woz and a mainframe for Markkula. This followed the trend that new media tend to imitate old media.

Radio began as vaudeville over the air, while early television was radio with pictures. For most users (though not for Woz) the microcomputer was a small mainframe, which explained why Apple's first application for the machine was an accounting pack age and the first application supplied by a third-party developer was a database—both perfect products for a mainframe substitute. But the Apple II wasn't a very good mainframe replacement. The fact is that new inventions often have to find uses of their own in order to find commercial success, and this was true for the Apple II, which became successful strictly as a spread sheet machine, a function that none of its inventors visualized.

At $3,000 for a fully configured system, the Apple II did not have a big future as a home machine. Old-timers like to reminisce about the early days of Apple when the company's computers were affordable, but the truth is that they never were. The Apple II found its eventual home in business, answering the prayers of all those middle managers who had not been able to gain access to the company's mainframe or who were tired of waiting the six weeks it took for the computer department to prepare a report, dragging the answers to simple business questions from corporate data. Instead, they quickly learned to use a spreadsheet program called VisiCalc, which was available at first only on the Apple II.

VisiCalc was a compelling application—an application so important that it, alone justified the computer purchase. Such an application was the last element required to turn the microcomputer from a hobbyist's toy into a business machine. No matter how powerful and brilliantly designed, no computer can be successful without a compelling application. To the people who bought them, mainframes were really inventory machines or ac counting machines, and minicomputers were office automation machines. The Apple II was a VisiCalc machine.

VisiCalc was a whole new thing, an application that had not appeared before on some other platform. There were no mini computer or mainframe spreadsheet programs that could be downsized to run on a microcomputer. The microcomputer and the spreadsheet came along at the same time. They were made for each other.

VisiCalc came about because its inventor, Dan Bricklin, went to business school. And Bricklin went to business school because he thought that his career as a programmer was about to end; it was becoming so easy to write programs that Bricklin was convinced there would eventually be no need for programmers at all, and he would be out of a job. So in the fall of 1977, 26 years old and worried about being washed up, he entered the Harvard Business School looking toward a new career.

At Harvard, Bricklin had an advantage over other students. He could whip up BASIC programs on the Harvard time-sharing system that would perform financial calculations. The problem with Bricklin's programs was that they had to be written and rewritten for each new problem. He began to look for a more general way of doing these calculations in a format that would be flexible.

What Bricklin really wanted was not a microcomputer program at all but a specialized piece of hardware—a kind of very advanced calculator with a heads-up display similar to the weapons system controls on an F-14 fighter. Like Luke Skywalker jumping into the turret of the Millennium Falcon, Bricklin saw himself blasting out financials, locking onto profit and loss numbers that would appear suspended in space before him. It was to be a business tool cum video game, a Saturday Night Special for M.B.A.s, only the hardware technology didn't exist in those days to make it happen.

Back in the semi-real world of the Harvard Business School, Bricklin's production professor described large blackboards that were used in some companies for production planning. These blackboards, often so long that they spanned several rooms, were segmented in a matrix of rows and columns. The production planners would fill each space with chalk scribbles relating to the time, materials, manpower, and money needed to manufacture a product. Each cell on the blackboard was located in both a column and a row, so each had a two-dimensional address. Some cells were related to others, so if the number of workers listed in cell C-3 was increased, it meant that the amount of total wages in cell D-5 had to be increased proportionally, as did the total number of items produced, listed in cell F-7. Changing the value in one cell required the recalculation of values in all other linked cells, which took a lot of erasing and a lot of recalculating and left the planners constantly worried that they had overlooked recalculating a linked value, making their overall conclusions incorrect.

Given that Bricklin's Luke Skywalker approach was out of the question, the blackboard metaphor made a good structure for Bricklin's financial calculator, with a video screen replacing the physical blackboard. Once data and formulas were introduced by the user into each cell, changing one variable would automatically cause all the other cells to be recalculated and changed too. No linked cells could be forgotten. The video screen would show a window on a spreadsheet that was actually held in computer memory. The virtual spreadsheet inside the box could be almost any size, putting on a desk what had once taken whole rooms filled with blackboards. Once the spreadsheet was set up, answer ing a what-if question like "How much more money will we make if we raise the price of each widget by a dime?" would take only seconds.

His production professor loved the idea, as did Bricklin's ac counting professor. Bricklin's finance professor, who had others to do his computing for him, said there were already financial analysis programs running on mainframes, so the world did not need Dan Bricklin's little program. Only the world did need Dan Bricklin's little program, which still didn't have a name. It's not surprising that VisiCalc grew out of a business school experience because it was the business schools that were produc ing most of the future VisiCalc users. They were the thousands of M.B.A.s who were coming into the workplace trained in analytical business techniques and, even more important, in typing. They had the skills and the motivation but usually not the access to their company computer. They were the first generation of businesspeople who could do it all by themselves, given the proper tools.

Bricklin cobbled up a demonstration version of his idea over a weekend. It was written in BASIC, was slow, and had only enough rows and columns to fill a single screen, but it demonstrated many of the basic functions of the spreadsheet. For one thing, it just sat there. This is the genius of the spreadsheet; it's event driven. Unless the user changes a cell, nothing happens. This may not seem like much, but being event driven makes a spreadsheet totally responsive to the user; it puts the user in charge in a way that most other programs did not. VisiCalc was a spreadsheet language, and what the users were doing was rudimentary programming, without the anxiety of knowing that's what it was.

By the time Bricklin had his demonstration program running, it was early 1978 and the mass market for microcomputers, such as it was, was being vied for by the Apple II, Commodore PET, and the Radio Shack TRS-80. Since he had no experience with micros, and so no preference for any particular machine, Bricklin and Bob Frankston, his old friend from MIT and new partner, developed VisiCalc for the Apple II, strictly because that was the computer their would-be publisher loaned them in the fall of 1978. No technical merit was involved in the decision.

Dan Fylstra was the publisher. He had graduated from Harvard Business School a year or two before and was trying to make a living selling microcomputer chess programs from his home. Fylstra's Personal Software was the archetypal microcomputer application software company. Bill Gates at Microsoft and Gary Kildall at Digital Research were specializing in operating systems and languages, products that were lumped together under the label of systems software, and were mainly sold to hardware manufacturers rather than directly to users. But Fylstra was sell ing applications direct to retailers and end users, often one pro gram at a time. With no clear example to follow, he had to make most of the mistakes himself, and did.

Since there was no obvious success story to emulate, no re tail software company that had already stumbled across the rules for making money, Fylstra dusted off his Harvard case study technique and looked for similar industries whose rules could be adapted to the microcomputer software biz. About the closest example he could find was book publishing, where the author accepts responsibility for designing and implementing the product, and the publisher is responsible for manufacturing, distribution, marketing, and sales. Transferred to the microcomputer arena, this meant that Software Arts, the company Bricklin and Frankston formed, would develop VisiCalc and its subsequent versions, while Personal Software, Fylstra's company, would copy the floppy disks, print the manuals, place ads in computer publications, and distribute the product to retailers and the pub lic. Software Arts would receive a royalty of 37.5 percent on copies of VisiCalc sold at retail and 50 percent for copies sold wholesale. "The numbers seemed fair at the time," Fylstra said. Bricklin was still in school, so he and Frankston divided their efforts in a way that would become a standard for micro computer programming projects. Bricklin designed the program, while Frankston wrote the actual code. Bricklin would say, "This is the way the program is supposed to look, these are the features, and this is the way it should function," but the actual de sign of the internal program was left up to Bob Frankston, who had been writing software since 1963 and was clearly up to the task. Frankston added a few features on his own, including one called "lookup," which could extract values from a table, so he could use VisiCalc to do his taxes.

Bob Frankston is a gentle man and a brilliant programmer who lives in a world that is just slightly out of sync with the world in which you and I live. (Okay, so it's out of sync with the world in which you live.) When I met him, Frankston was chief scientist at Lotus Development, the people who gave us the Lotus 1-2-3 spreadsheet. In a personal computer hardware or software company, being named chief scientist means that the boss doesn't know what to do with you. Chief scientists don't generally have to do anything; they're just smart people whom the company doesn't want to lose to a competitor. So they get a title and an office and are obliged to represent the glorious past at all company functions. At Apple Computer, they call them Apple Fellows, because you can't have more than one chief scientist.

Bob Frankston, a modified nerd (he combined the requisite flannel shirt with a full beard), seemed not to notice that his role of chief scientist was a sham, because to him it wasn't; it was the perfect opportunity to look inward and think deep thoughts without regard to their marketability.

"Why are you doing this as a book?" Frankston asked me over breakfast one morning in Newton, Massachusetts. By "this," he meant the book you have in your hands right now, the major literary work of my career and, I hope, the basis of an important American fortune. "Why not do it as a hypertext file that people could just browse through on their computers?" I will not be browsed through. The essence of writing books is the author's right to tell the story in his own words and in the order he chooses. Hypertext, which allows an instant accounting of how many times the words Dynamic Random-Access Memory or fuck appear, completely eliminates what I perceive as my value-added, turns this exercise into something like the Yellow Pages, and totally eliminates the prospect that it will help fund my retirement.

"Oh," said Frankston, with eyebrows raised. "Okay." Meanwhile, back in 1979, Bricklin and Frankston developed the first version of VisiCalc on an Apple II emulator running on a minicomputer, just as Microsoft BASIC and CP/M had been written. Money was tight, so Frankston worked at night, when computer time was cheaper and when the time-sharing system responded faster because there were fewer users.

They thought that the whole job would take a month, but it took close to a year to finish. During this time, Fylstra was show ing prerelease versions of the product to the first few software retailers and to computer companies like Apple and Atari. Atari was interested but did not yet have a computer to sell. Apple's reaction to the product was lukewarm.

VisiCalc hit the market in October 1979, selling for $100. The first 100 copies went to Marv Goldschmitt's computer store in Bedford, Massachusetts, where Dan Bricklin appeared regularly to give demonstrations to bewildered customers. Sales were slow. Nothing like this product had existed before, so it would be a mistake to blame the early microcomputer users for not realizing they were seeing the future when they stared at their first VisiCalc screen.

Nearly every software developer in those days believed that small businesspeople would be the main users of any financial products they'd develop. Markkula's beloved accounting system, for example, would be used by small retailers and manufacturers who could not afford access to a time-sharing system and preferred not to farm the job out to an accounting service. Bricklin's spreadsheet would be used by these same small businesspeople to prepare budgets and forecast business trends. Automation was supposed to come to the small business community through the microcomputer just as it had come to the large and medium businesses through mainframes and minicomputers. But it didn't work that way.

The problem with the small business market was that small businesses weren't, for the most part, very businesslike. Most small businesspeople didn't know what they were doing.

Accounting was clearly beyond them.

At the time, sales to hobbyists and would-be computer game players were topping out, and small businesses weren't buying.

Apple and most of its competitors were in real trouble. The personal computer revolution looked as if it might last only five /ears. But then VisiCalc sales began to kick in. Among the many customers who watched VisiCalc demos at Marv Goldschmitt's computer store were a few businesspeople— rare members of both the set of computer enthusiasts and the economic establishment. Many of these people had bought Apple lis, hoping to do real work until they attempted to come to terms with the computer's forty-column display and lack of lowercase letters. In VisiCalc, they found an application that did not care about lowercase letters, and since the program used a view through the screen on a larger, virtual spreadsheet, the forty column limit was less of one. For $100, they took a chance, carried the program home, then eventually took both the program and the computer it ran on with them to work. The true market for the Apple II turned out to be big business, and it was through the efforts of enthusiast employees, not Apple marketers, that the Apple II invaded industry.

"The beautiful thing about the spreadsheet was that customers in big business were really smart and understood the benefits right away," said Trip Hawkins, who was in charge of small business strategy at Apple. "I visited Westinghouse in Pittsburgh. The company had decided that Apple II technology wasn't suitable, but 1,000 Apple lis had somehow arrived in the corporate head quarters, bought with petty cash funds and popularized by the office intelligentsia."

Hawkins was among the first to realize that the spreadsheet was a new form of computer life and that VisiCalc—the only spreadsheet on the market and available at first only on the Apple II—would be Apple's tool for entering, maybe dominating, the microcomputer market for medium and large corporations.

available at first only on the Apple II—would be Apple's tool for entering, maybe dominating, the microcomputer market for medium and large corporations. VisiCalc was a strategic asset and one that had to be tied upfast before Bricklin and Frankston moved it onto other platforms like the Radio Shack TRS-80.

"When I brought the first copies of VisiCalc into Apple, it was clear to me that this was an important application, vital to the success of the Apple II," Hawkins said. "We didn't want it to appear on the Radio Shack or on the IBM machine we knew was coming, so I took Dan Fylstra to lunch and talked about a buy out. The price we settled on would have been $1 million worth of Apple stock, which would have been worth much more later. But when I took the deal to Markkula for approval, he said, 'No, it's too expensive.'"

A million dollars was an important value point in the early microcomputer software business. Every programmer who bothered to think about money at all looked toward the time when he would sell out for a cool million. Apple could have used owner ship of the program to dominate business micro-computing for years. The deal would have been good, too, for Dan Fylstra, who so recently had been selling chess programs out of his apartment. Except that Dan Fylstra didn't own VisiCalc — Dan Bricklin and Bob Frankston did. The deal came and went without the boys in Massachusetts even being told.

Rest of book is not public / published

Chapter 1 : One Person's Need For a Personal Computer

Kildall s Nautical School

My grandfather Harold was a seafaring man and ran the Seattle to Singapore route as Chief Mate of a 1920's steamship.

Lumber shipment from Everett, a port north of Seattle, to Singapore was a lively trade. After the longshoremen finished loading Grandpa Harold's ship, he noticed a mongrel dog pacing the pier. That mongrel decided quite boldly to board grandpa's ship. He named the dog "Hector."

Hector became grandpa's sidekick on the voyage to China. even lying beside him at the midnight watch while Harold scanned the horizon and worked navigational positions of his ship in crossing the Pacific Ocean.

Grandpa's freighter arrived at Singapore harbor and Hector became agitated. On impulse, Hector jumped overboard near a Sampan rowing by. Well, his real owner was riding on that Sampan and scooped that mongrel from the water. Two weeks earlier, it seems Hector's master had sailed from Everett on his own ship"s schedule.

Hector was nearby that day of sailing at Everett, but certainly not aboard his master's ship, and that sailing could not be delayed. Hector's little dog-brain recognized the situation, and scented grandpa's ship that was going to the same place as his lost master.

The story appeared in Reader's Digest in 1957. I always liked this story, and it was true, and grandpa told us many others like it. This is a book about computers. Why tell a dog story? I promise that it will be relevant, but not for awhile.

Harold returned from sea duty in 1927, maybe partially because my grandmother, Gwendolyn, would go to sleep with tears nearly every night he was away. Grandpa started a navigation school in Seattle, first located at the University of Washington, then later moved to downtown Seattle. It was called Kildall's Nautical School and, for fun, it became known as "Kildall's College of Nautical Knowledge." He taught merchant seamen to become officers onboard commercial ships. His students became Third Mates, Second Mates, Chief Officers, Masters, and Pilots. Grandpa Harold taught in that school to within a week of the day he died at 92 and educated over 30,000 students, many of which could not multiply zero times zero when they started.

I must admit that although I am one of grandpa's admirers, he was a bit disorganized. The Coast Guard did all the exams on his students, so he'd quiz his students afterward on their test questions. After a few years, his nautical school had bits and scraps of paper nearly everywhere. These scraps recorded questions and answers, kind of like Cliffs Notes, but randomly unsorted throughout the school's office as if arranged by a small explosive charge. Still, the "college" was known as the best in the country.

My dad, Joseph, followed in grandpa's wake and worked his way to a Master Ocean license, the top rank in merchant shipping. World War II came about, and Joe started with the "college" as an Instructor. **The school was valued by the government because Harold and Joe trained the skippers of the Victory Ships that dodged those Wolfpack U-boats to bring supplies to the war effort in Europe.**

Dad took all those scraps of Coast Guard Q&A and put them into a voluminous card catalog. He had every question that the Coast Guard examiners could conceive, right there in that office. Not that the students were just prep' don the questions, because there is no doubt that they were trained in every aspect of Marine Navigation and Engineering. The Coast Guard did not have a chance against the two. Harold and Joe's students knew their business quite well, indeed.

Being in the lineage, I was expected to continue the tradition of the Kildall School. which I did for a time in the early 60's. Grandpa, then slightly retired, lectured on Magnetism and Compass Correction and, on occasion. circled the cigarette smokefilled room to check his students' progress as they slaved at finding the answer to yet another of the school's "exercises."

Grandpa, dad, and I were a good trio. To my personal benefit, I learned the mathematics of Navigation and Trigonometry, and spent extra hours canvassing the dusty, rare old books of the school's small library that covered such oddities as "How to Rebabbit the Bearings of a Double Acting Steam Engine."

To navigate you take "sights." A sight is a reference point to a celestial body, such as a star. You look through a sextant, find the proper angle, and then look at your chronometer. Next, look in the Nautical Almanac for that exact time and date. Use standard, but tedious, calculation forms to plot the result. That tells you where you are on the face of the earth.

Joe often described a "machine" that he wanted to build. "You punch-in the navigation data and turn the crank, and out comes the position of your ship." He envisioned properly-shaped cams and gears to do this, because he was a mechanical person by nature. It wasn't until the microcomputer was invented that the "crank" was truly feasible. It's a connection we'll pick up in 1972 at Intel Corporation in Santa Clara. Strangely, dad's dream formed a link all the way to today's personal computing and operating systems.

In the early l 960's, I worked at the Kildall "college," and became heir-apparent to the Kildall School throne. Instead, I decided to get an advanced education. This didn't set well with my father, because it caused a discontinuity in the lineage. Not only that, my high school grades were so bad that there seemed no possibility of entry to college.

However. I wrote a petition to the Regents and cited my work as an Instructor at the Nautical School. **Because of the Nautical School's recognition, I gained entry to the University of Washington in 1963 by that petition, but by an entirely too close of a margin.**

The Kildall Nautical School taught me processes that high school hadn't. Such as the ability to do mathematics of a sort and, most important, the mental tools to dissect and solve complicated problems, and to work from the beginning to the end in an organized fashion.

However, the practice of Navigation. in the traditional sense, was fast becoming obsolete. My father tried to nix my leaving the Kildall Nautical School. but the challenge of becoming a full-fledged teacher was too much to ignore.

I signed for the University of Washington. My intent was to become a high school teacher. I didn't ever teach high school. Now that I have passed through three teenagers and their studies. I believe that Divine Providence did me a personal favor. But, I worked very, very hard and got top grades. I think that's because most of my fellow students were party animals, and I, being a "greaser" in high school, had that out of my system by college. During those first years at the UW, I studied the basics of Mathematics. Meanwhile, I worked at Harold and Joe's Nautical School. It was hard, rewarding, and fun.

My father was a precise man. His handwriting was unscripted block perfect. His workmanship could not be excelled whether it were in the schoolroom or over a lathe in his workshop. He took on a project to build an 83 foot yacht when I was only sixteen, and it was sort of finished when he died thirty years later. I think the project was too big, but that was the way he lived.

CHAPTER 2 Seattle and the University of Washington

Computer Life at the "U-Dub"

Taking courses at any university is a problem for someone who didn't study that hard in high school. Ok, so I had some good background in mathematics from

the Navigation School, such as fundamentals of trigonometry, but, hey, go take on calculus.

All those guys from the seventeenth century, like Keplar and Newton came up with some complicated stuff. They did it to figure where the planets would be. That made it easier to navigate. And, navigation let people do business. and it let them make money. There were two other subjects that I enjoyed, and these came into play in later years. My father 's precision in drawing brought an interest in art. Pencil drawing became a part of my life and allowed me to promote and exercise the graphics tools developed by Digital Research in later years. I studied art at that time, and I enjoy it today. Another was history. Mathematics, art, and history. These are three topics that kept my interest. We all have some. And, they are the mead of one's existence.

In 1963, at the "U-Dub," as it was called, I found myself in the evolutionary transition between mechanical calculation and digital computers. My first class in Numerical Analysis in 1964 was from a professor in his eighties. This nice old gentleman was retiring, and not too soon in my opinion, as he seemed quite feeble and at somewhat of a loss of memory. He taught the trade of computing with Marchant calculators. A Marchant calculator is a big, black machine, about three times the size of a typewriter. It has a giant carriage on top with about ten holes with little mechanical numbers that pop up in the slots. There are buttons all over the front with digits, decimal points, and keyed symbols that multiply and divide to control this mechanical nightmare.

They used these Marchant calculators for Numerical Analysis, starting in about the I 940's. A business would hire rows and rows of Marchant calculator operators to compute so-called "Finite Differences." This led to tables of figures that let you, for example, toss a mortar precisely into your enemy's backyard.

You sat there and pushed those keys while the mechnicals made a host of noises by cranking and grinding who-knows-what, until the rattling stopped. You got a number. You put the number on a form, and eventually, with enough numbers and forms, you got a result. Sometimes the resulting number was correct.

These operators also made tables to figure where the Sun, Moon, stars and planets would be at a particular time, much like the tables that solved the navigation problems that we talked about eariler. In a sense, dad's navigation "crank" was somewhat inconveniently embodied in the Marchant with a "form" alongside.

A Blunder

By the way, here's a little story about Numerical Analysis. Numerical Analysis is based upon computing formulas by stepwise refinement to within as close a tolerance as possible.

What that means in English is that the more you push all those damn Marchant keys, the closer that mortar will get to your neighbor's rear door when you decide to launch it. So, if the real answer is to aim that mortar at a 41 .34567 angle, and the Marchant operator computes it as 41 .34566, you have an "error" of 0.0000 I. Then, you decide if that is acceptable (which it is not for bankers, but might be for a Sergeant, or Boeing Corporation).

But, for myself, I always liked the term "blunder" used in Numerical Analysis. A blunder, contrary to an error, means that you didn't push the proper keys on that Marchant or, possibly pushed them in wrong order, or you didn' t write down numbers properly as they appeared. In short, you screwed-up. I like the word "blunder."

So, I make this proposal (with tongue placed properly at cheek level), that one should refrain from stating that "I have an 'error ' in my program," for that would mean that one is within .0 I% of a working program that has no error. This makes no sense, because ail engineering managers know that this .0 I % doubles the project length.

Instead, we engineers must from forever onward refer to a program that operates incorrectly as one that has a "blunder." Under interrogation as to the progress of your project you state quite objectively and in clear tone,

"Sir, my Device Driver does not yet operate, it has a Blunder."

Blunders are not errors. They are simply mistakes you made in writing your program. C'mon, your boss knows everyone has "blunders." Hey, he probably spilled a glass of wine on the hostess at that party last night for the company president.

Blunders can go on for years, and your manager will be completely confused, but knowingly accepting. A blunder. Try it tomorrow. Trust me.

Transition to Computers

Coincidentally, my study-student-friend, Dale Leatherman, stopped me outside our class a few days after that old professor retired. He opened his notebook and showed me an unpunched computer card. At the top was printed "FORTRAN STATEMENT." He told me that this computer stuff was going to be a "big thing." That was 1965.

Dale and I took courses together in computer studies, starting with assembly language programming for the IBM 7094. For you computer youngsters. here's the way it worked.

You walk into the keypunch room with your two-foot long cardboard box of FORTRAN STATEMENT cards. Then wait in line to get to a keypunch machine. Finally, someone tires of typing, and you get a seat.

Each card in that stupid cardboard box is like a single line on your computer screen today. I don't even want to think about it, because you young guys have it all too easy. But, my Computer Psychiatrist told me that "eet izz important to get zees feelingks about der dumbkopf keypunches out in der open." All us oldtimers remember that the keypunch machine is like a typewriter, but it shuffles cards through its mechanism and stamps rectangular holes in a column below each character. You leaf through your box, alter each necessary card, and then relinquish your keypunch to the next anxious student. Then, take your precious box of cards to the shelf outside the computer room and wait and wait and wait.

The computer room hides the IBM 7094 with SAC-like security doors. Computer operators, trained in "Grumbly IO I ," sit behind that door, attending to their work and throwing down coffee without even their own notice.

I know this because I spent about 1,312,467 hours looking through that little peephole window to see if the operator would arise from his or her throne to go to the restroom and possibly retrieve my box of punched cards on the way back into SAC.

If you stayed around very late at night, you might get a "turnaround" of an hour or so to get the printout. The program usually didn't work, so it was back to the keypunch. To know what it was like, go back to the heading for this section, "Transition to Computers," and re-read it until you fall soundly asleep.

Getting into Compilers

Getting into Compilers

Let me start with a short note about why I write about compilers. First, they are my primary interest in computing. Compilers, when perfected, can be elegant to the point that you want to paste a printed listing on your wall, like artwork. Ok, so you have to be into writing compilers to get my meaning, but when your compiler works, you are very proud and want to show it off.

But, for most engineers, compilers are simply mind tools. Our minds are too limited to write complicated programs that do things like GEM, Windows, or D-Base without them. Compilers make programs that computers understand from programs that people understand. They are sort of like natural language translators who sit in a business conference and make English into Japanese.

The UW bought a new computer. It was a Burroughs B5500. This computer, an offshoot of the English Electric KDF-9, was unique. It was designed to run ALGOL (ALGOL stands for Algorithmic Language, an improvement over FORTRAN, and the precursor of today's Pascal language).

The B5500, although today severly outdated, is a "stack machine." That means that data is held in temporary memory that is built and discarded as its program runs (that's the way the "C" programming language works today). The B5500 and ALGOL were the basis for compiler design at Stanford University and the model for Bill McKeeman's work on XPL. And, XPL led to Intel's "defacto standard processor."

During my graduate studies, I used Bill McKeeman's XPL. It was called a compiler- compiler. XPL is a program that makes compilers. What you do is plug-in rules of syntax, much like grammar rules of English but constrained to the rigidity of computer languages.

Linguistics and Compilers

For me, linguistics was only word phrase games, like the word "wind" that can mean a stiff breeze, or what you do to your watch to make it keep time. (No, don't answer with "I change the battery." I'm talking about the old windup kind, Jeez.)

Noam Chomsky was a well-known Linguist who helped define the difference between "syntax" and "semantics" in natural language through his work on "Transformational Grammar." He studied natural language by allowing for sentences like this.

"He broke the window with his little sister"

(and, I always liked this next one)

"He fed her dog biscuits"

(or, how about this one that took me awhile to figure out),

"Time flies like an arrow"

Just like the word "wind." these sentences have multiple meaning, but the form, or syntax, is correct in English.

The connection is simple. Chomsky's theories and symbolism for natural language helped in processing newly defined computer language forms. Take a look at those phrases. The syntax is correct, but the meaning is ambiguous.

McKeeman's XPL processed computer statements, not English, but it's sort of the same idea. That is, XPL looked for proper form (syntax) in the computer language, not the meaning (semantics). In order to make XPL work. you added more ALGOL programming to cause the compiler to "understand" each statement that you parsed.

Unlike natural language, there can be only one meaning to a computer sentence. That's why you cannot just "tell" a computer what to do. It needs to process the exact meaning of each thing you say, in context. And, even in context, the meaning may not always be clear. Here's an example.

"Hey, you know old George. He's down near the crossroads. Yeah, well he done got a new Intel 486 with a Connors Drive and 16 Megabytes of RAM. An' old George just booted it up this momin', don't ya know. But 'pears old George wam't too happy with it, 'cause he coundunt get that dum Microsoft Windows to work."

"Worse yet, George to!' me it near broke his left foot and scuffed his new pair of Lucheses that he'd been savin' up fur near a month or so. don't you know fersure. But. he's feelin' better now 'cause that 'dum 486 is stuck setting thur in that oak tree up yonder, an' it seems awork a mite better now, don't you know."

Get my point? Ok, you might retort "hey, man, I've got a computer that understands English at home." Fine, its vocabulary of, say, about 1000 words must be trained by the operator speaking those words over and over. It's like having a baby that's started to talk. And, what it eventually understands is a severe subset of English, with vocabulary limited to very special functions and people, such as mom and dad.

Unfortunately English. and other natural languages evolved somewhat inconsistently and constantly change. That's why we have computer languages that adhere to very strict rules of syntax and semantics.

The Computer Chronicles

"Ok. Gary, why are you bringing up the Computer Chronicles in the middle of a discussion about languages and compilers," you might say. First, I wish to brag about my seven-year stint with this FINE Public Broadcasting Show (viewed by over a million people, syndicated throughout the USA on every PBS channel, I might add, and even shown in China, and ... Ok, I'll stop).

Wait..., wait. .. , don't stop reading. I mean, after all, I was a STAR! But, for reasons quite unfathomable to me, I was not asked to place my computer-worn fingers in that cement down on Hollywood Boulevard at Gruman's. Hmmm ... could it be my acting? Someone wrote in once and said, "Gary is very good as co-host of Computer Chronicles," but it looked like my mother's handwriting.

Ok, so I'll make it relevant. I agree that the Chronicles is not in the timeline of our discussion, but a particular show one day demo'd how natural language doesn't match computer languages.

Stewart Cheifet hosted and organized the show, and I co-hosted which means "show-up Gary, on time, hey?" Stewart selected the computer companies to be taped in three segments for each show. He came up with the latest in modems, printers. PC's, games, and whatever else imaginable during those seven years from 1982 to 1989. However, there was that one "demo" that stood out, done by "Jim" from company "X" (the real names are withheld for a degree of sympathy). I want to tell you more about Chronicles itself before I bring out Jim.

Stewart, the crew, and I did twenty-six shows per year, taped in the studio at the College of San Mateo. The deal was that I drove from Monterey, California, to the college on a Saturday morning, arriving at about 9:00AM. We taped two shows on those Saturdays, so I needed to be there for thirteen Saturdays each year.

Now, work this backward. Hmmm ... It takes two hours to drive from Monterey to San Mateo, so that means I've got to leave home at 7:00AM, and, since I must wear a suit, that translates to 6:00AM. This is not a good time on Saturday for a DRI Standard Issue Party Animal.

No big deal. we taped the "opens" in the morning, and I could make as many mistakes as necessary because our director, Peter. would open the intercom and gently ask "did you like the take?" Considering my oft condition. the answer was usually "no," and Stewart and I would do another pass at it.

I can say, respectfully, that Stewart nearly always made it through his thoughts on those opens, for we had no teleprompters. He did flub a few times in the seven years. I enjoyed it immensely when he did. I give him a 96% on those "opens."

After that, we rolled in the marketing managers and promoters to set up hardware, usually two or three at a time, and do Q&A and demos.

Stewart is a connoisseur of fine software and hardware products. And, being trained in Law, he could talk endlessly, without great effort during taping. But, I believe he made a singular error by selecting Jim for the show that day.

Jim came on the set with his "HAL 9000." I was, of course, curious. This appeared to be the name of the talking computer in Arthur C. Clark's movie, 2001, but I gave no judgement. Jim's black box sat there before me on the set, with our director, Peter in the editing booth rolling tape. "Mr. Jim," I asked, "just what does your HAL 9000 do?" I awaited a response that I knew was coming, but sincerely did not want to hear.

"Yes, Mr. Kildall, my computer talks and thinks, just like the HAL 9000 in the movie 2001. It uses Artificial Intelligence."

"Just like the HAL 9000?" Yes, "Just like the HAL 9000." Well, I was of course taken aback by such a wondrous feat of the time, as talking and thinking machines were quite out of my realm. Jim continued with, "My HAL 9000 talks to you, makes judgements, and comes to conclusions, all by itself."

If you've viewed the Chronicles show, you realize that the segments are short. So, we got right into it. "Mr. Jim, can we get a demonstration of this immensely intelligent machine that you brought here today?"

Jim wanted Stewart, a person with extensive broadcasting experience, and quite a clear speaking voice, to "talk" to HAL. Ok, so the cameras are still rolling, right? Stewart surrounded himself with a headset and microphone while Jim "booted" HAL.

"Stewart. say hello to HAL." Stewart. in his finest speaking voice obeyed and said "Hello." In fact. he did this about eight or ten times and got random responses in computer-trashed English. like:

"Igmm Very Sorgy, Plse Say it Agan." or "I can not ungderstand wat youg are sayging," or "Plse say that one morge tigme" or "Igmm Very Sorgy, Plse Say it Agan."

Well. I can say with little reservation that the demo was not going well for Jim or HAL. So, changing the subject, I touched carefully on the topic of Artificial Intelligence with Jim after that debacle to fill the segment, because I surely did not want to repeat it.

The crew was going to lunch. so we broke down the set. and I was left alone with Jim. He wanted to do the segment over, because he felt " it just didn't go right." I can't imagine how he could have come to this conclusion, do you?

Tape's not rolling, and the set's hot lights are off. I patted Jim on the back, and assured him that it would show well, but he should get HAL's feelings on it to make sure.

I have not talked with HAL since, but that demo was the biggest waste of video tape, computer and TV cable time that I had ever seen. But, for the good, Jim and his friend, HAL, showed that natural languages and computers are not a good fit. and that was worthwhile.

I'll never forgive Stewart for setting up that segment; although I will allow a bunch of other PBS programming transgressions over the years of the Chronicles that are private to Stewart, the crew, and myself. The events will not be publicly disclosed unless under severe bribery, for which I show a weakness at times. I had fun with those guys at KCSM.

Oh, by the way, if you ever happen to watch re-runs of the Chronicles, take a look at the background. It makes us look like we're located in a building at San Francisco overlooking the Bay. Most "guests" were quite surprised to find us in the basement of the College of San Mateo studio on a set with a fake window and picture of the Bay. I'm not complaining. It was quite a nice set, with the exception that the Transamerica Building is shown half-finished in that picture background and remained so for the seven years that I did that show.

Booting a Computer

Ok, so let's get back to the PC industry.

I don 't know about you, but the word "booting" a computer seemed a little strange when I first used that B5500 at the UW. To "boot" you turned on the power of that room-sized computer and stuck-in a single punched card into the card reader. The card had a little itty-bitty program that read another program from disk, and that program read another, and so-forth, and that started the whole computer.

So, the origin of the phrase "to boot your computer" comes from the word "bootstrap," which means to "pull yourselfup by your own bootstraps." Today, this is the small built-in program in a computer system that lets you load your operating system.

But, "bootstrapping" has also been used to describe the process of writing a compiler for a language using the language itself. It's just like writing ALGOL in ALGOL, or "C" in "C." And, it's hardly different from describing English in English.

Where do you start bootstrapping? Consider this. "C" is written using "C," and there was a programming language before "C" called "B," and "B" was written using "A." What do you think "A" might have been? Hmmm ... assembly language perhaps?

Bootstrapping the Industry

Compilers for computer languages, like FOR1RAN and COBOL, were made to help take away the pain of assembly language programming. They make computer statements in their strict rules of syntax into the instruction set of the computer.

Computers in the 60's didn't have much main memory, and "assembly language programmers" could do a better job at fitting memory than automated compilers. So, high-level languages supported by those compilers were not considered efficient even by the late 60's.

There is a direct trace from the two Burroughs B5500s at the UW and Stanford University through to compiler development in XPL for the Intel chip set, and on to CP/M and DOS.

High-level languages like ALGOL on the B5500 changed the trend of using assembly language for "efficiency." For example, you really couldn't write a B5500 assembly language program unless you were a real technonerd. In 1966, the UW hired me to maintain the ALGOL compiler, and that old B5500 became my learning machine. I saw a ton of sunrises over that Computer Center.

It was a great personal computer. I'd just plant a sign that said "B5500 Down For Maintenance" at about midnight and open shop again at 6:00 AM for student programs. Ok, so that's not fair. but that was a long time ago, in a galaxy far-far away, so don't blame me, 'cause I was just a kid, Ok?

During this "maintenance," I'd take the whole B5500 system down. "reboot" and play in the B5500 ALGOL sandbox. In my own defense. I did, on occasion, actually fix some errors (sorry, "blunders") in the ALGOL compiler. However, Iseriously doubt that I ever deserved all of those paychecks.

I will personally attest that this ALGOL compiler was, for the day, an elegant piece of code. ALGOL was written in ALGOL, and this got everyone's attention. thirty years ago that was a neat hat-trick. How do you write a compiler in its own language? You have to have an ALGOL compiler to write the ALGOL compiler, right? Chicken and egg.

Solution? Write a small compiler using another computer, such as that KDF-9. This little program compiles code for the B5500 small ALGOL subset. Then, you start writing the ALGOL compiler using that subset. gradually improving the compiler step-by-step. Chicken and egg again.

It's called "incremental improvement," and that's how all complicated programs are written. You just gradually improve to reach your goal in small steps. That's how humans solve problems. Hey, it's not such a big deal. After all, that's how Mom Nature solves problems as well.

Systems Programming for that B5500

Locally, it was only Dick Hamlet and myself there to take care of the B5500. Dick is a very astute computer person. He is a tall, sandy-haired, bushy-faced guy with freckles and piercing eyes. He did not tolerate incompetence whether it be intellectual or otherwise, but rewarded you with a smile when you sparked his interest.

He understood the B5500 Operating System like no one I ever knew, and he gave a lecture to the new Computer Science Group at the UW where he described the thickness of a listing as a measure of the complexity of an operating system. I never forgot that line, because it was so often true. I always used that measure to determine the output of my own engineers in later years.

I learned much from the architecture of the B5500 computer. In particular, I learned about data structures for organizing disk drive information.

In later years, I extrapolated from these B5500 data structures to create the first personal computer operating system, which I named CP/M.

The Age of Timesharing

There was a new technology in the works. It was called Remote Access. At the UW, we used a data communications setup attached to the B5500. Only the privileged Oracles could hook up. There were eight ports tied to the B5500.

Dick Hamlet had a direct connection to the B5500 from his office, which I coveted dearly. There was another in the computer room. Some officials had the others, and I was never allowed entry there. But, they never used the lines, so it didn't matter anyway.

A modem was connected to a third port. I got the university to buy a portable acoustic coupled modem for me. This let me make a phone call to the B5500. "Big deal," you say, "I do this every day using my 2400 baud built-in modem, connected to Compuserve, Prodigy, Dow-Jones, and places that I don't even know I'm connected to .... "

Cut me some slack. Hey, that was almost thirty years ago. This acoustic coupler, or "modem" as we call it today, was grey, and about the size of a shoe box with two holes in the top to hold the handset, surrounded by foam padding that came ajar immediately after shipment from the factory, which, by the way had usually gone out of business directly after the sale.

Hook your teletype to the acoustic coupler. Then make a phone call to the B5500. Stick the handset into the coupler. Ok, then you "log-in" using your secret password that everyone seemed to know anyway. If you' re lucky, you see the sign-on:

University of Washington B5500 Remote Access, Version 1.0

*

The asterisk was the "prompt" to tell you to type more stuff. But. quite frankly, that 110 baud acoustic coupler failed more often than not, and the message appeared like this

Uni#44sityof Wash,:gton B5522 #@%%8<< version?[5 z

Oh, great response Mr. B5500, and this is only at 110 baud with a stupid phone stuck into the coupler with foam cushions falling out everywhere.

So, you stuff that phone and foam back into that lame coupler, a little harder this time, and try again, most often viewing a similar response and being not slightly entertained by the random letters and symbols that the coupler, the B5500, and AT&T had collectively selected. Dial again, and hope for the best.

I'm sorry, dear reader, that I got a little worked up over that. Phew .. ., Ok .. , ok, .. I'm really Ok now. I have occasional episodes of "Early Remote Access Shell-Shock." My Computer Psychiatrist tells me that the effects will decrease with time once I come out from under my computer desk when I try to use Compuserve.

The UW Computer Center bought one of those workhorse Teletype Model 33's. It's a heavy, mechanical device that, by observation. shouldn't operate any more than a Boeing 747 should be able to fly.

I built a grey wooden box for that teletype and went around showing how remote access to a computer system over telephone lines works. Or, I should say,

didn't work. I went to Seattle Pacific College in 1966 with my modem and teletype encased in its package on rollers.

The demonstration was typical. I couldn't log-in. The computer was down, or for some other reason didn't respond. Following that, I never gave a live demo again. But, Dick Hamlet believed in remote access to computers through timesharing and formed a company to provide that sort of service.

The Computer Center Corporation

I mention the Computer Center Corporation, or C-cubed, as it was called, because it predicated an interesting series of events involving Bill Gates, Paul Allen, and myself.

Dick Hamlet, Monique Rona *[See **Monique R Rona (born 1928)**]*, Carl Young *[See **Carl Garland Young (born 1926)**]*, director of the UW Computer Center, and my undergraduate professor David Dekker *[See **Dr. David Bliss Dekker (born 1919)**]* started C-cubed. It was one of the first timesharing computer companies in Seattle and used Digital Equipment Corporation's DEC PDP-I Os. C-cubed, located near the UW, was in business for only a short time and folded.

C-cubed depicted the mentality of the late sixties. No one wanted to manage punched cards, nor did they wish to wait at the operator's door in favor of a sampling of program output. Instead, timesharing became the watchword. Remote access to the B5500 sparked Dick, Monique, and David's interest in creating the Ccubed business.

There were two kids from Lakeview High School who broke into Dick's DEC PDP-IOs and stole passwords. This way, they could hook up to Dick's computers from a remote teletype and use it for free. The two kids were Gates and Allen.

Don't vilify Gates and Allen for this activity. Breaking in was not that hard. It was like stealing candy from the comer computer store. And, it was theft of the very basic sort.

Dick was one of the best systems programmers I had ever run across, and it didn't take him long to discover the theft of time on his machines. He found the culprits and cleverly allowed Gates and Allen access to C-cubed, so that he could recode and test the operating system to help prevent illegal access.

Dick explained how Gates and Allen did it. It's fairly simple. They "logged-in" to his DEC PDP-10 system from a remote location using a valid account and password. A sample limited account was given to Lakeview students by C-cubed, mostly through Monique's interest in the school. Well, the DEC PDP- I 0 used virtual memory that swapped RAM to disk. This left data in memory pages that were given to other programs. Dick's machine wasn't heavily used, so most of memory had operating system data structures like passwords, still lying around in memory. Gates and Allen just dumped "pages" of reassigned memory to their computer terminal and watched for things that looked like passwords. Once they found a few. they simply used them at no cost to themselves. The reason that I consider this theft is that I, even being a very good friend of both Dick and Monique, could not afford to pay C-cubed timesharing charges, although, I sincerely wished to do so.

Dick found the Gates and Allen scam when a customer complained about a bill for services when, in fact, no services were rendered. He fixed it by zeroing memory pages when they were swapped out and released. That took extra computer time but stopped the banditos.

I was attending the UW then. I noticed a couple of kids programming at C-cubed one day. They were Gates and Allen. I ran into them then, and again several years later.

There was not enough commercial interest in remote access to computers around Seattle in those days. Besides, Boeing Airplane Company was going broke, and, as a result, so was Seattle. C-cubed was hit squarely by this and folded. In those late I 960's, you could drive south on 1-5 and, stuck almost in front of you, was a huge billboard that read

"Last One Out, Please Tum Off The Lights"

The New U-Dub Computer

That old IBM 7094 computer was getting a bit tired in 1965. So, the university tasked the Computer Science team of professors, headed by Dr. Hellmut Golde [See **Hellmut Paul Oscar Golde (born 1930)**], to find a new one.

I, now being Hellmut's Ph.D. student and general lackey, was, in tum, tasked with creating a set of "benchmark" programs. The Computer Center normally pumped out FORTRAN programs for the students, so I made several boxes of sample programs and put them on magnetic tape. That was our benchmark. Our UW team went to IBM at Yorktown Heights and then visited CDC and General Electric for throughput timing using our test.

The CDC 6400 severly won that benchmark and ran about two to three times the capacity of the IBM System/360. Hellmut and the team made the decision, and the UW contracted for the CDC computer.

Three top IBM salesmen immediately approached the President of the university, Dr. Charles Odegaard, and told him of the error of his ways, and that he would be humiliated by the decision he had made, and that the decision should be reversed.

Odegaard listened patiently to the IBM salesmen and, when they were completely done, immediately sent them packing, with contracts flying loosely about in the room. I respect Odegaard for not succumbing to the IBM "end run" that was so prevalent in those years.

But, I got a call while at the UW "Hub" from my then wife Dorothy. She said I had received a draft notice. Uncle Sam wanted my bod for the Vietnam War.

Going to War

The Viet Nam War was unfortunate for me personally, and for the world in general. Being selected to serve in the Army wasn't particularly appealing because I had been offered the opportunity to enter the first Master's Degree Computer Science class in 1967. There were to be twenty of us in this first class of CS there, and a letter from the Draft Board wasn't really in the grand scheme of things.

I went to the draft center, like many of you did, and was probed by the government doctors in the chilly line of recruits. One doctor asked if I knew that I had a heart murmur. Relieved at the possibility of exemption, I said, "No," but it turned out his question was rhetorical. The doc asked everyone that one. I was sworn in to serve in the Army. Damn, all of a sudden visions of rice paddies flew through my head.

Of course, I tried a quick pass at the Draft Board to convince them to allow me to get to a master's degree. They laughed and told me there was not a chance, "you're going to war, young man."

Well, my dad had friends who were captains in the Navy. I know you 're not supposed to use connections, but, quite frankly, I didn't want to get shot at.

Dad connected me to one of his buddies, and I joined the Navy with his recommendation. That satisfied the Draft Board. Not only that, I got a reprieve to finish my master's degree while I worked toward my commission as an officer.

It took two summer sessions at Officer Candidate School at Newport, Rhode Island in 1967 and 1968 to complete my training to become an ensign.

When I got there, I didn't like the training one bit. They cut off all my hair on the fi rst day. It took all summer to grow back. They worked us. Guys dropped out. I told myself to never look back on OCS and think it was Ok. It wasn' t. It was a bummer. I was destined to become an officer on a destroyer tossing shells into the forests of Viet Nam.

Oh. by the way, this is a neat story about OCS. They had a course in navigation that we took daily. Well, of course, no one knew that I had been teaching it for years. So, when the weekly quiz came, I finished it momentarily after going over the problems twice. I'd turn it over to the instructor, and he'd visibly take notice that they were always all correct answers. Good old Harold and Joe at that Nautical School had something to do with those test scores. I graduated with the Technology Award, and nobody knew why.

The Navy allowed me to continue my education to the master's degree in 1969. During that year before graduation, I taught seaman apprentices how to win their data processing stripes. We had weekly Navy Reserve meetings at an ex-WW-II building on the south of Lake Union in Seattle.

These were horribly boring events. I headed the data processing squad, and we skipped-out right after colors and drove to the Naval Station at Sand Point, just off Lake Washington. There they had the oldest IBM collators, sorters. and machines programmed by inserting plug-in wires into "patch boards." We all got through Reserves, and my guys all got their stripes. Most important, we didn't have to march all evening between "colors" like the other guys.

Going from the UW to "War"

Graduation day came in December of 1969. I was to receive my M.S. with honors, for which I was very proud considering my high school grades. However, the prospect of a destroyer tour as a lowly Lieutenant JG seemed a dismal prospect.

But, the President of the university, Dr. Charles Odegaard, had been impressed by my work in their new Computer Science Department. Recall, I had been the technical advisor in selecting their new CDC 6400 computer. Dr. Odegaard was on the Board of the Naval Postgraduate School at Monterey, California. Then, Captain Williams of the Reserve Officer Training Corp at the University of Washington, who I had never met, called me for his counsel.

The Captain asked me to take a seat opposite his desk. You vet's know that it is very important that you take the seat that the Captain tells you to, and I obeyed, assuming a position of seated attention in that chair. Captain Williams, in his khaki regulars, looked me squarely in the eye. "Mr. Kildall, I understand that you are graduating in Computer Science." I was not aware that President Odegaard had made a private recommendation to the Captain.

[NOTE - Of course Odegaard went to Dartmouth College ! https://en.wikipedia.org/wiki/Charles_Odegaard I wonder if he was friends with Peter Kiewit Jr?]

"Mr. Kildall, you have a choice to make." Well, the Captain proposed that I could either be an officer on a destroyer off the coast of Viet Nam or take the post as an Instructor in Mathematics and Computer Science at the Naval Postgraduate School at Monterey, California. This particular question made me understand the length of a microsecond. "Well, sir, I would like dearly to serve my country in battle, but I think I shall take the second option, if you please."

Captain Williams warned that if I taught at the Naval Postgraduate School, I would probably not reach the level of Admiral. I took a pensive stance for a moment and then told him that I would accept that risk.

CHAPTER 3 The NPS Helps Foster Microcomputing

Life at the Naval Postgraduate School

The Naval Postgraduate School, generally referred to as the NPS, is located at Monterey, California. It is a very good school in all respects and placed at a magnificent oceanside locale. Although I have not had the opportunity to make a visit to Viet Nam, I am quite sure that Monterey has a nicer coastline.

They teach only postgraduate courses at NPS. The students are mostly U.S. Navy Military, with a smattering of foreigners. The students are dedicated. They have to be. Some of the foreign students were said to be put before a firing squad on return to their homeland when they failed. I don't know if this was true, but I was a bit more lenient on them because of that.

Strangely, the NPS contributed significantly to the rise of microcomputing in the early l 970's.

Breaking from the UW's B5500 computer mainframe was tough for me. Recall that I had the B5500 to myself for hours at a time. The B5500 had been my rather large personal computer. Now, I had to use that IBM System/370 at the NPS, just like any other programmer.

Not only that, it didn't have any good high level language. So. here I am. stuck with a stupid System/370, no high level language, and no direct access to the computer. This was a technonerd nightmare.

But then. Old Captain Williams' words rang in my ears, and I took particular solace in the fact that I was not floating over the swirling seas of the Gulf of Tonkin with no computer at hand whatsoever.

Ok. so first you make friends with the computer operator at NPS's Computer Center. Then. make friends with the systems programmers. I met a nice lady, an astute programmer, Kathy Strutynski, who was later instrumental in programming upgrades to CP/M, and with relationships between Microsoft and DRI many years later.

The NPS accorded me a few specific tasks. First, I was to teach computer courses. Second. I was to be on the "Crypto Staff," and third I was to take inventory of liquor at the Officers' Mess.

I enjoyed the teaching with a passion, but the crypto duty over that three years resulted in only one message that transmitted a notice to an Admiral "that a free turkey was due to arrive on Thanksgiving." It took about an hour for me to decode that one.

I never could figure the inventory. But, there was a little lady named Mabel Johnston, who, at about her 75 years of age, could figure it quite nicely. She patiently showed me journals of numbers in column after column because I, being the Naval Officer In Charge, was required to verify her numbers to the

penny.

Honestly, I just watched her and believed her additions, subtractions. allocations to inventory, taxes, and on and on and on. That was a risk, but after all, you must believe in a grandmother, right?

Mrs. Johnston knew the ropes. Years later, "Visicalc" on the Apple took some of the toil. Do you think that Bricklin's Visicalc made a substantial contribution to the success of Apple's PCs? I think so, because ifl could have had Dan's spreadsheet at the time, I'm sure I would have impressed old Mrs. Johnston. But, somehow, I don't think she would have taken notice of any sort. She would've just moved to the next page in her ledger.

How to Program the IBM System/370

Here I am at the Naval Postgraduate School in 1970. Ok, better than Viet Nam, but not better than the U-Dub's 85500. The NPS had just installed a System/370, one of the first delivered by IBM.

The IBM System/370 was an enigma for me. No languages. No access. I started with Nicklaus Wirth's PL/360, a sort of high-level assembly language. It wasn't any good. Wirth went on to define the Pascal programming language which was a considerable improvement. Faced with no reasonable high-level language softwaretools, I went to PL/I. IBM's runaway attempt at displacing FORTRAN and ALGOL.

How to be a Professor at NPS

As for my role at the NPS, some considered me a hard teacher. I don't think I was. A bunch of students said I was. So judge for yourself.

I often taught the Data Structures course. The class was called CS3 l l l. To combat boredom, one semester on a first day, I entered the classroom and told the thirty-odd students that "we will now have a pop-quiz." Everyone must place their books and notes on the floor and they, being good Naval Officers, did so.

The problem that I proposed was to write a program that would "perform symbolic differentiation and simplification of polynomials to any order."

Well, I can tell you right now that was a huge order. And I, being professor-incharge, may have barely gotten into a solution within that fifty minutes. Cruel, but I wanted to get a line on how my students thought about the problem of problem solving. I didn't really expect them to get to a solution of any sort whatsoever.

Those students worked away at that problem for fifteen minutes, at least. Then I said, "stop what you are doing now. I want you to think about how you are solving this problem, and what mind tools you are using at this moment."

Of course, the whole thing was a ruse, and the students were completely relieved, because not one could come close to a solution on that first day. I asked how their thought processes were working, and several of those students came up with good and different ideas on problem solving.

Ok, so I had this pop-quiz, right? The course proceeded through the semester, and I didn't give any other tests or quizzes. We worked entirely on problem solving, using Knuth's algorithmic notation and McCarthy's LISP List Processing symbolic programming language. At the end of the semester, I gave a final exam. There was only one question.

I don't think was being a mean professor. Do you?

Why did this group of students after two more semesters with me as their professor, post a finely emblazoned plaque at the NPS's Trident bar room that stated all too clearly:

"Class of 71 , Kildall CS3 l l I, CS 3112, CS3 l l 3, Three Time Losers‥

Ok, the guys did get their ultimate revenge. According to military protocol. I was required to usher the graduating students to their seats in King Hall. Although I was allowed civilian attire during classroom sessions, my ushering duty required my officer's dress uniform.

I had to let my "Three Time Losers" leave ten minutes early from the classroom, just before their graduation, to allow me time to change from my civvies to my officer's uniform. These were the same guys that I had taught all those three semesters. They knew that Kildall had to usher, and they enjoyed every minute. They knew, that by rank, I must cater to them.

I detected a few snickers here and there in the process. I have kept all their names in a special folder and intend sometime in the not-to-far-off future to reevaluate their grade scores as a basis for retracting a master's degree, or two. After all, I have kept all of their old tests, and I may have made an omission of some sort. Right?

It was a difficult study for these officer students, but, in the end, everyone graduated with their degrees, so I guess it couldn't have been all that bad for us.

But, in early 1972, my three-year obligation to the Navy was over. And, just as I had refused Captain William's option to go to Viet Nam, I declined both a "re-up" and the option of Naval Reserve meetings in a moment that may have been shorter than that "microsecond" that got me to NPS in the first place.

Back to School at the U-Dub

I kept my association with the NPS after my stint in the Navy. The Computer Science group at the NPS asked that I return as a professor, but I felt the need to complete my education.

Dr. Hellmut Golde [See **Hellmut Paul Oscar Golde (born 1930)**] at the University of Washington Computer Science Department had allowed that I continue work toward the next degree by "remote" from NPS while in the Navy, so I was prepared to finish my Ph.D. in fairly short order.

My research interest centered in compiler code generation. Recall, that this means that a compiler reads computer language statements and makes it into another program that the computer understands. Take, say a program with I 000 statements and make a computer readable form of it. The computer readable form might take 400 bytes of RAM. A good "optimizer" might reduce this by 25% to 300 bytes. This saves storage and generally makes the program run faster.

The name of this analysis is "Global Flow Optimization." You figure out how data values will vary or stay stable at each decision point in a program. Then you use that information to make small programs instead of big ones. That's called compiler code optimization.

Well, there was quite a bit of theory out there. Some was by John Cocke at IBM, and Harry Huskey at UC Santa Cruz, for example, and some was by Jefferey Ullman who was well-published in the Mathematics of Computer Science. But, I thought I had a process for flow optimization that was a general theory,

covering nearly all of the current techniques.

A quick program in McCarthy's LISP convinced me of the correctness of my process, and I then spent several months with McKeeman's XPL system making a production compiler. The process worked, but I couldn't create the mathematics to back it. I just knew that it worked, but that's not enough. This all happened in 1971 .

But, then I developed an algebraic model of my process. This so-called "algebra" is not like the one we study in high school, but instead is a mathematical modelling theory that lets you describe sets of objects (like program data values), and formulate ways to combine these objects (like through program branching and joining).

Well, my formulation was good, but I couldn't prove my central theorem, and that made my approach worthless as far as academicians were concerned. That was a basic problem, because, after all. I was trying to get the Ph.D., right?

I got out of the Navy in early 1972, without a proof of my theorem, and returned to the University of Washington, but my brain was about broken by then. None of my professors could help, and some were beginning to believe that my central theorem wasn't in fact true at all. This was not encouraging.

A Story About Light Bulbs

Ok, so I'm at the UW and I couldn't discover my proof. I just sat and sat and sat in my UW grad student office, resting my head in both hands, until my eyes shut by themselves late that evening. Nothing.

Then, in an instant the proof came to me. I wasn't even paying attention to it. I awoke in an instant and wrote the entire proof of my central theorem, not finishing until sunrise. I guess that's why they put light bulbs over cartoon characters. The discovery of this proof was one of the grandest experiences of my life, except, of course, for the time I visited Niagara Falls One Day.

It was a general theory, and it was quite elegant, if you will allow me to say so. Jefferey Ullman was a professor at Princeton University and picked up the thesis almost immediately after it was published. He liked it and elaborated on the theory in his own books.

Jeff is an astute Computer Scientist. He invited me to lecture at Princeton. which I did, and then to lecture again when he moved to Stanford. He is now Chairman of the Computer Science Department there. Jeff is an easy-going sort, and a great contributor in promoting the mathematics of the science of computing.

The NPS kept a civilian position open at the school, and I returned there with the rank of Associate Professor. Eventually, they gave me tenure. Tenure, as most of you are aware, means that you have a job "forever" or unless you die first. That is quite a nice deal in education, especially since the charts showed that NPS was second only to Stanford in salary in the entire nation. Not only that, education is one of the greatest scams concocted by mankind. Here's how it works.

You arrange to start your class at 11 :OOAM (9:30 wake-up, eh?). NEVER schedule more than one class of a different topic on the same day, for this makes you prepare two different lectures in your allotted ten minutes before each class, and if this rule is violated, it can be stressful and confusing in the classroom.

And, You allow your classes to be scheduled for at most three days of the week, although two is preferable. On all other possible occasions, use lowly, rarely paid "lab assistants" to off-load your heavy pressure.

You get holidays on every conceivable occasion. like Spring vacation, President's day, all summer, Christmas for a month, and then throw in Ground Hog's day for dessert.

Oh. yeah, I forgot that you must "Publish or Perish. right?" Well, that 's easy enough. Get the university to buy you a Macintosh (say "sir, the portable, if you please?"). Then, on holiday in Hawaii, get a good ole' charge on them there batteries and make up an Industry Opinion Newsletter of your own! Publish every month, make a few bucks, and call it something like, "A Wholistic View to the Future of Computers in the Next Decade." See, this works. It's kind of like Nostradamas, 'cause you don't really have to be specific; you make your money over the first few years, 'cause you' ve got a DR. on the front of your name, so people sort of believe you.

That Newsletter also prompts invitations to speak that sometimes pay up to $1000 per evening, plus a free meal (don't ever speak at a symposium where they don't pay for everything, including the airfare - you can try for First Class, but I never got it).

I apologize to you readers who are teachers by profession, but c'mon. it's kind of a cushy job at times, right?

Departing from "Cush"

Leaving this sort of job situation to move into industry was one of the hardest decisions of my life. So, I just didn' t make it. I'm good at that.

Best of all, the NPS faithfully encouraged one day of consulting work in the Silicon Valley area each week to bring the latest info back into the NPS classroom. I shall remain eternally grateful to the NPS powers-that-be for that particular edict.

CHAPTER 4 Silicon Valley Micros

New Technologies

Ed McCreight came from Seattle. He joined the budding group of researchers at Xerox PARC, the Palo Alto Research Center. Ed knew about my thesis work and invited me for a visit in 1972 on one of my "consulting" days. Alan Kaye was there, and they showed me their work. One was Alan's SmallTalk that used high-resolution graphics and windows.

I was nonplussed by their new computer design, called the ALTO, but their white background terminal with black character fonts of a wide variety drew my attention. I didn't know it at the time, but this was to foster the entire desktop publishing industry.

PARC's new technologies were severely interesting, but having no background in graphics, and having an intense interest in compilers, I thought of their efforts as futuristic oddities.

efforts as futuristic oddities.

A Small Ad

Back at the NPS, I had a co-teacher named Gerry Barber. Gerry was tall. thin. pale, and balding at 25. He spoke with a lisp that you accommodated in time and rode his bicycle to school. He wore horn-rimmed glasses and pens lined up in a little case that he carried you know where. He swooned in class one day, and I had to revive him and take him to his home.

Gerry read every journal. He gleaned a small advertisement from Electronic Engineering Times. It read "Intel Corporation offers a computer for $25." Well, considering that the NPS IBM System/370 cost about $3M, I thought that was a pretty good deal, and Gerry agreed. This was mid-1972. And. by the way, I'd never heard of this little chip company, called Intel, at the time.

No matter. This is Econ' 101. Ok, the chip was only a 4-bit computer, called the 4004. And, it really wasn't $25, unless you bought about 10,000 of them. The cheapest "development system" was about$ 1000, and that didn't include the Model 33 Teletype that nearly even completely worn-out, ran about $700.

Still. that was a lot less than the IBM System/370 with a list price of three mill', and certainly not within the budget of an up-and-coming Associate Professor with a wage of $20,000 per year.

Intel sent me the specs for the $25 i4004 chip. This was a very primitive computer by anyone's standard, but it foretold the possibility of one's own personal computer that need not be shared by anyone else. It may be hard to believe, but this little processor started the whole damn industry.

The 4004 was fallout from a project Intel did for Busicom, a Japanese calculator manufacturer. Instead of building a specialized chip for Busicom, they designed a single-chip microprocessor controlled by a small read-only-memory (ROM).

Think of the mentality of the time. You used a timesharing system that varied in its response depending upon the time of day (those of you who use Compuserve or Prodigy know what I'm talking about). These little 4004 computers promised constant response time; although, the problems they solved were about as big as the chip.

There in 1972. My dad's navigation "crank" had arrived in the Intel 4004, but there appeared some major programming work to get the crank to actually work.

Intel built a little foot-square blue box with a PC board on the top. The PC board included one of those little 4004's. You could write programs with the "development system," and I had to have one. It was called the SIM4-01 .

Oh. by the way, I enjoyed working with Gerry Barber. He was an honest, religious. intelligent man. He was astute.

An Introduction to Intel Corporation

I can say without reservation that the instruction set of that $25 Intel 4004 chip was the worst ever. Its only redeeming value was that it was dirt cheap in quantity, and that drew designers to use it in tons of dedicated applications like portable inventory data collection and specialized electronic monitors.

It was impossible for me to come up with $1700 for the SIM4-01 development system and teletype, so I wrote a simulator on the IBM System/370 that faked the operation of the 4004. Then, I went to work on dad's navigation crank. Well, this turned out to be quite a problem, because navigation requires computing "trig" functions, like sines and cosines, and that little processor had none of these. for sure.

I spent a few months writing trig functions for that little processor using my simulation on the IBM System/370. I didn ' t actually own a 4004, I just used my simulator on the System/370 to check and debug all of my trig functions.

All my 4004 programs came together, so I called Intel to see if I could scam a development system. I ran into Bob Garrow at a time when he was a fairly wellpromoted engineer at Intel. I tried to sell him on the notion of trading my 4004 simulator for one of his $1000 SIM4-01 development systems.

Being a hardware nut, Bob didn't want the simulator. But, he did want the trig routines, because they were the beginnings of a "library" for the 4004, of sorts. Hey, I didn 't care, I just wanted a SIM4-01 .

Bob always had a smile on his face, and I must have looked hungry for food and hardware. He craftily took me to his favorite Italian lunch spot in Santa Clara, fed me cannelloni, and worked to get a few "extras" in trade for that SIM4-01. In reality, I didn't mind, because I kept thinking about that $3M IBM computer that was my alternative.

Incidentally, five years later, Bob left Intel to found Convergent Systems, a nicely successful computer company in the Santa Clara Valley at the time.

The Age of Intel s 4004 Microprocessor

The SIM4-01 used the 4004 chip but included power supplies and support circuits. It had 1024 bytes (not kilobytes) of RAM for data storage, and up to four 256 byte (not kilobyte) ROMs for programs. We're talking primitive here.

Actually, these were not strictly ROMs. They were called EPROMs. an acronym for electronically erasable and programmable read only memories. They have a quartz window right over the chip. Shine an ultra violet light there for enough time, and the data goes clear. By the way, you have to scam a bunch of 1702 EPROMs because they were a hundred bucks each.

I met Tom Pittman on a journey to Intel. To me, Tom is the first personal computer developer and user. (Later, Tom wrote Tiny-C, for which he is best known.) Clever Tom wrote a "monitor" for the 4004, and a small assembler that actually ran on the SIM4-01 itself.

This, in effect, was the first self-hosted single chip microprocessor development system. Tom's "monitor" took 257 bytes, one more than the 1702 EPROM could hold. He condensed that to 256 bytes without changing the monitor. Ask him how he did it if you run into old Tom, or if you ask me, maybe I'll tell you.

Using a Teletype Model 33

I am going to have fun with this one, because only the diehards have ever experienced the infamous Model 33. It has a big case that holds the printer mechanism and a roll of, normally, yellow paper. On the left side is a paper tape device, half of which is a ··reader" that, of course, reads holes punched in that tape. The tape encoding is Ascii. just as we use today.

The second part of the paper tape device is the punch. The punch. of course, made the holes. So, to edit, you make a program and punch a tape. If you make an

error, you "backspace" and put "nulls" (all laterally punched holes). Then, start typing agam.

Ok, you' re saying the next part appears a bit tedious, but if you are a true computer person, you must go through it. After all, we "pioneers" all had to do this stuff two decades ago so that you can enjoy your sweet little lap top while cruising placidly over Colorado at 37,000 feet in UAL First Class. Hey, c'mon, just a little bit of torture for all our troubles in those days.

Here's how programming a 4004 worked in 1972. You buy a UV light, if you can find one, to erase the 256 bytes of memory in a 1702 EPROM for storing your program. Then plug in Tom's monitor and three EPROM assembler.

Stuff some paper tape into your teletype and type in each program line. Use that mechanical paper tape backspace to null out some holes in the tape if you make a mistake. (How'd you like that teletype today in your lap at 37,000 feet? Ok, so keep reading.)

Now you've got a program of sorts on that paper tape. Run the paper tape back through the teletype at ten characters per second, one more time. To understand I 0 cps, remember that a very good typist works at 100 words per minute. That's 600 characters per minute, or just about the speed of a teletype.

You get some "syntax errors" from the assembler. So, run that tape back through the reader and stop to "edit" while the paper tape punching is making a new tape, and hope the hell you don't make a mistake again.

Eventually your program is syntax error free, which, by the way, doesn't mean it works right, right? In any case, out pops another paper tape in Intel "hex" format of the machine code.

(I know that you are totally bored with this discussion about paper tape, but I also know that if you have gotten this far, you have enough curiosity to continue. Think of it as paybacks from those of us in the last generation.)

Take out Tom ·s four EPROMs that hold the monitor and assembler and put in the "hex programmer" that loads up I 702's. Putting these EPROMs in and out would often bend a pin. but by this time, I was so adroit that accidents were normally limited to poking my finger with one of those prongs a time or two every day.

Next, take your EPROMs that have been cooking under that UV light and stick them one at a time into the EPROM programming socket. Run that hex file paper tape that you just got into that stupid teletype again and load each EPROM. This takes 30 minutes to erase the EPROM, and five minutes to load the 256 bytes into that 1702. Meanwhile. reassure yourself that this is a lot cheaper than the IBM System/ 370 downstairs.

For reference, an average JFK to SFO flight takes about six hours. That's the time it takes to program twelve EPROMs of 256 bytes each, or a total of 4,096 bytes of memory. That laptop you ride around with these days loads program memory of that size in about I/5 of a second. Hmmmm ... 6 hours compared to I/5 of a second. Not bad. Ok, if you scammed enough of those I 702's you could erase four or five of them under that UV at the same time.

Are you bored with this discussion? Good. Hey, you can get through this in five minutes. It took us a year, Ok? Paybacks.

Let's go back to the 4004. So, now that you've written your 4004 assembly language program, you're ready to test. Stick in your newly programmed EPROMs, push the RESET button on the SIM4-0l and GO. Usually nothing happens. That's because there is a bug in your program. But, there's no way to tell where that bug is. The SIM4-0l just sits there and doesn't do anything.

There were a couple of LEDs on the SIM4-01 . To find your error, you reprogram and use those LEDs to see how far your program gets before "crashing." That usually took a day or two, or the equivalent of a few flights from coast-to-coast.

I wrote a simple BCD (binary coded decimal) calculator for the National Computer Conference in 1972 using this little SIM4- 01. It took a month, and by the time it was done, I had sat and stared at the teletype so long that I had to put it on a little pedestal, so I could stand and debug, for obvious medical reasons which I will not go into at this time.

So, next time you have an itsy-bitsy bug in your program running under Borland C++ with the Turbo Debugger, don't come to me for sympathy, because I'll just give you a SIM4-0I and stick you on an airplane with an old sixty pound teletype that I happen to have in my garage.

I built a briefcase computer using the 4004 in l 972. I'd take this around for demos, and people really liked it. It may have been the first personal computer. Once, I took this to a lecture at the University of Washington. A guy named Tom Ro lander was in the audience, and he became enthralled with this little computer. Tom was to play an important role at DRI.

Grace Hopper 's 4004

Here's a story about a lovely lady, Captain Grace Hopper. Actually, she became an Admiral after I met her.

Grace Hopper was self-proclaimed to be the first programmer, and I believe her. She was quite elderly when I met her, but wore the crisp dress uniform of the Navy each time I saw her.

She helped invent COBOL, that business language used throughout the world today. She was a brightly clever, petite gray-haired lady with a wit and brain sharper at her age than most who were half her's. She was like having a channing grandmother who could talk your socks off about computers. Quite a combo, indeed. All her stories were true, captivating, and always drew a crowd.

Captain Grace gave lectures at universities throughout the country. At the NPS, she handed-out strips of thin wire about a foot long that became known as "The Grace Hopper Nanosecond." That piece of wire she gave to those students showed how long it took for electricity, or the speed of light to travel in a millionth of a second. It was a good illustration for everyone to see the limits of linear computing.

Grace became a friend. I was helping to "man" the Intel booth at the National Computer Conference in the Fall of 1972, and Grace came by proudly in her military dress. She gazed sneakily at me with those eyes that shown in that brilliance of hers, though her outward appearance was of frail demeanor. With stealth, Grace reached into her purse and brought out an Intel 4004 chip, then whispered to me "this is the future."

Alas, Captain Hopper was forcibly retired some months later. After all, she was well past mandatory retirement. The Navy was her life, and I'm quite sure she was devastated. There is a good ending though, because popular naval opinion brought her back as an Admiral.

For analogy, Grace had become like the Blue Angels Flying Team that does fly-bys and airshows for the Navy, making a bunch of noise and burning lots of kerosene.

kerosene.

The Navy supports the Blue Angels to recruit Navy flyers. The Navy supported Grace to recruit the interest of college students in bringing their talents to the technology of computing for the Navy. She did a fine job of that. By the way, she was waaaay less expensive than the "Angels" to maintain.

Bugs in Your Programs

It's fun to tell you the story about how Grace and her buddies invented the word "bug" as it applies to an error in a computer program. She worked with John Von Neumann in the days of World War II. John worked on solving numerical analysis problems, like the kind that let you toss mortars around.

They had a repeating error in one of their programs while operating their "relay" computer. Remember, relay computers were built with mechanical clappers driven by magnetic solenoids. That was in the 1940's, before the vacuum tube machines, and certainly before the transistor and chip computers.

Upon investigation, they found that some of nature 's real live bugs were in there, preventing the relays from closing properly. So, next time you have a "bug" in your program. try "Raid." Oh, and by the way, that is why CP/M's debugger was called the "Dynamic Debugging Tool," or DDT for short.

The Age of the Intel 8008 Microprocessor

I began to work for Intel as a one-day-per-week consultant in 1973, following my somewhat discouraging experiences with the i4004. I was now the proud owner of a used Model 33 Teletype that I got by trading my 4004 teletype diagnostic program to a repair company in Cupertino.

Intel had developed a new microprocessor chip. It was called the i8008. The 8008 was more advanced, but that wasn 't hard to achieve, considering the design of the 4004. It was an 8-bit computer with a "Von Neumann" architecture. That means that the program and data are all in the same memory, like current PCs today.

The software group at Intel in 1973 consisted of Bill Byerly, Ken Burgett, and myself as a consultant**. I was under contract to develop a simulator for the Intel 8008, much like the one I had done for the 4004, under direction of microprocessor manager Hank Smith.**

The microprocessor group at Intel occupied the space of a not too large kitchen at the time. Bob Noyce, founder of Intel walked through occasionally with his usual smile. and gave a few pats, but they were token gestures. His interest was in making I 101 RAM chips in the other section of Intel's only factory on Bowers Avenue in Santa Clara.

Noyce and Computer Games

Bob Noyce was a clever, somewhat silent, gray-haired guy who mostly wore a white lab coat to cover his casual demeanor. At first, I must admit that I liked him because he was a pilot. But, there is one fun experience that I had with Bob, and this is not intended in any way to put him down, as I admired him greatly for all his contributions.

One engineer at Intel in 1972 had developed a graphics chip set that controlled a little triangular space ship. It mimicked the game of "Space Wars" that had traditionally operated on DEC minicomputers.

Space Wars worked like this. You control the velocity and direction of this graphics "space ship" using keyboard control. The ship operated under those Keplar's Laws of Motion around a "sun" that would pull it in if your spaceship came too close. I thought that it was a good idea for a commercial consumer game.

Later, I used my 4004 briefcase computer to build a simple game of "Nim" that used the 4004's LEDs. Stan Mazor, one of Bob's gurus, suggested we approach Noyce with the idea of making game computers. This was in 1973, before such things were popular. Noyce peered at the LEDs blinking away on my 4004. He looked at Stan and me and said, bluntly, that the future is in digital watches, not in computer games.

I suspect Bob's interest in watches came from Intel's then recent acquisition of "Microma," the first digital watch company. By the way, just like I scammed the SIM4-0 I. I worked a deal with Bob for a Microma digital watch that I was very proud of. in trade. of course. for more software.

But, unfortunately for Intel lots of other companies, mostly Japanese, also figured out how to make digital watches and flooded the industry. Intel dropped the Microma business. I don 't know if gaming would have been successful through Intel, but I have thought about Bob Noyce's decision that day.

He had the beginnings of a Nolan Bushnell-style industry that was sacrificed for a digital watch business that didn't take hold. I'm certainly not saying that Nim was the right game. but the Space Wars chip set was on the right track. It's fun to speculate.

Bob was a friend. He, like all of us, made some decisions that are right, and some that could have made the future unfold in a different manner. But, most of all, Bob treated his people with dignity. He had the foresight to build an industry in microprocessors. I was very sad when he died recently. I sent a note to his wife, Ann. I liked them both very much.

The NPS Microcomputer Lab

Microcomputers became the new "thing to study" at the Naval Postgraduate School in 1973, and the faculty backed me to get the funds to build a laboratory for them. We set up some SIM4-01 stations, then went to the Intel Intellec 8 development systems.

It turned out to be quite a nice lab that jump-started a bunch of guys like Glenn Ewing, who helped engineer the IMSAI computer, and Gordon Eubanks, who founded Semantec, along with a bunch of other projects with the Navy at the Naval Undersea Center at San Diego, and the test center at Keyport, Washington.

We taught the NPS students how to use micros. One project was a CMOS 8080 wristwatch computer that computed "partial pressures of nitrogen" according to standard Navy diving tables.

This means that a Navy diver could descend to a certain depth while the watch continuously monitored time at depth. Then, upon ascent, the diver looked at the LEDs on the watch to tell how long to remain at a certain level to avoid the "bends." Nice package, indeed.

It was a low power. obviously waterproof device, and is still used today. We used CP/M to make that software and others like it for the Navy. That little

Scuba computer was designed in 1975 and went into production for the Navy only a few years later.

A High Level Language for Microprocessors

Let's go back to 1973. I must admit that I spent more than the Postgraduate School allowance of a "day a week" on my consulting, but I will not admit how many. I lived in my Volkswagen van at night in the Intel Bowers Avenue parking lot after my eyeballs gave way.

One day, I knocked at the door of Hank Smith's office at Intel. He invited me in. Hank was the manager of our minuscule microprocessor software group. I told him that I could make a compiler for the 8008 so that his customers didn't need to use low-level assembly language. Hank didn't know what that meant, but I showed him how a customer could write:

X=Y+Z

and that would make several lines of assembly language. He immediately got on the phone and called a customer he was courting. The customer liked it, and Hank, with a smile, said to "go for it." I like corporate decisions like that.

The language I developed was named "PUM," and it used compiler technology of the time, based upon McKeeman's XPL. PIJM stands for a "Programming Language for Microcomputers," and is still used by Intel customers today, though largely supplanted by the "C" programming language. PUM allowed a microprocessor programmer to remove himself from the tedium of assembly language programming.

As spokesperson for high-level languages on those little Intel machines, I had to fight vigorously to show the advantages of the approach in public forum. It wasn't too difficult, because I often demonstrated that I could produce an effective program at ten times the hourly rate of an assembly language programmer using PUM, using about the same amount of program memory space. PUM became a success.

Meanwhile, Intel had developed the small computer system in 1974 called the Intellec 8 that I mentioned. It must have been the first commercial personal computer, although no one thought of it as that.

Toward Self Hosted PL/M

By "self hosted," I mean that program development and testing take place on the computer that sits directly in front of you, and the program you write can run on that same computer.

Unlike Tom Pittman's self hosted little development system for the 4004, PL/M used a minicomputer like C-cubed's DEC PDP-I 0. You write the program using the closest DEC PDP-I 0, run to the paper tape punch and get your "hex" file. Then, you program your EPROMs or load RAM using the paper tape. Messy, and not the right answer.

The Intellec 8 came with an EPROM "programmer" socket on the front, and standard with 4,096 bytes (not kilobytes) of RAM. You could make it l6K by adding three more memory boards at $1000 each. You used a good old teletype to make programs for the 8008 in much the same way as with Tom Pittman's 4004 monitor and assembler. And, Ken Burgett had developed a nice 8008 debugger called MONS.

I horse traded more software and got my own Intellec 8. Then, I got a loan for $1700 to buy a character video display and a huge printer. I was close to technoheaven. I now had a real personal computer that could actually be used to make real programs.

One of those programs for the Intellec 8 could be a compiler for PL/M that would operate directly on the 8008, rather than be tied to the expensive DEC PDP-10. This would make PL/M "self- hosted" on the Intellec 8.

But, there was a fundamental design problem. The 8008 had a "stack" size of eight return addresses. This means that only seven subroutines can be in effect before an undetectable overflow. And, this made it unusable for PL/M and lots of other microcomputer applications. But Intel, with Mr. Shima's help, came up with a solution.

The Age of the Intel 8080

Shima, as he was known to me, was a reserved Japanese chip architect. He had designed the Intel i4004, which for some reason, I did not hold against him any longer.

In 1973, Intel brought Shima back to their Bowers Avenue facility to upgrade the 8008. especially to take care of the short stack problem. Shima worked at his lab on his design. One day in late 1973, Shima hurried to the office where Bill, Ken, and I were programming. He said that the new i8080 was "running."

Of course. I followed in trail to his lab and found a poor assaulted microchip tethered by thin probes attached to some electronic monitors that must have told Shima something. There was a binocular microscope peering down into the middle of the mess.

Shima told me to take a look through the microscope. I saw nothing but a bunch of needle tips touching some apparently interesting spots on that chip. He told me that half his 8080 chip was running. Not wanting to break his stride, and not knowing what the heck was happening down there, I said, "Wow, Shima, that's really neat!"

Many people attribute Apple's entry with the Ile as the basis for the personal computer. But, I am of the opinion that Shima's little 8080 chip really started it all right then and there.

Ok, now Shima's got a pretty good microcomputer, called the 8080. Intel upgraded their Intellec 8 to a version they called the Intellec 8/Mod 80. It was truly a personal computer, although designed for development, with two exceptions. There was no large memory storage device such as the hard drives we have today. Second, the whole thing was waaay too expensive.

By the way, "backup" storage has two meanings in computing, so I should probably sort them out. Backup storage, in the beginning meant the big hard disk that stored program, data, and left-over student program output that you didn't ever receive, and, incidentally, may be yet awaiting. But, today a "backup" is a copy of the hard disk to something like a little tape drive.

To avoid confusion, I'll use the alternative term of "mass storage" to mean floppy disks and hard disks.

The Intel Intellec 8/80 showed an avenue to self hosted high level language development. I wanted severely to get away from the DEC PDP- I 0 cross-development and do PL/M compilation and debugging on the Intellec 8/80. I didn 't care about the expense, because I had already scammed my own Intellec, so I was only concerned about the lack of mass storage. And, hey, I had my own 9600 baud CRT (although I was still making payments in that area).

I had to solve the mass storage problem before PL/M could be operated independent from the DEC PDP- IO miniframe.

CHAPTER 5 The Advent of CPIM

The Quest for a Fast and Cheap Storage Device

So, the term "mass storage" means things like diskettes and hard drives today, but we just didn't have anything like that in 1973 that was affordable. The best was a high-speed paper tape reader and punch combination.

Some had proposed using cassette tapes rather than paper tape. I tried once to build a controller for a cassette tape in 1974, but failed miserably, thank God. For, if I had been successful, there would have been no CP/M, and certainly no MS-DOS.

I needed mass storage to support PUM development. Well, Memorex was just down the street from Intel. They had come up with the new "floppy disk" to replace those IBM punched cards we talked about. The floppy disk worked with IBM-style keypunches but made a disk instead of punching cards. (Incidentally, I don't know to this day why a floppy disk is a "disk," but a CD-ROM is a "disc.")

Getting back to the point, think about this. On the one hand, you have a teletype paper tape reader that processes at ten characters per second. Now, the floppy disk holds 250,000 characters and moves data at 10,000 characters per second. That's about the same as 2000 feet of paper tape, operating 1,000 times faster than that old teletype.

Quite a reasonable difference. Not only that. the diskette would, unlike a paper tape, instantly access any portion of the data without rewind or fast forward. That made Memorex's new floppy disk quite inviting for mass storage.

Those payments on my new CRT didn' t give any margin for a floppy disk drive at $ 1500. plus controller at $3000. But. Alan Shugart had started a small operation up the street, called Shugart Associates. Alan. also, was making "IBM Compatible" floppy disk drives. I went to Alan to scam one.

I misused my Intel credentials to get access. Finis Connor worked there as a marketing manager, and I got Finis to give me one of their old test drives. That poor drive was being used to evaluate MTBF (mean time between failure) and had a few hours on it. Like about 10,000. Finis gave me some new felt read/write head pads to replace the worn ones and sent me on my way.

Great. I've got this old, worn, 8 inch floppy drive. And, I don't have a "controller." Even ifI did, it wouldn't work in my Intellec 8/80.

See. you need some fairly complex electronics in that controller to make the diskette drive find certain locations and transfer data back and forth to the Intellec 8. I can tell you without reservation that I sat and stared at that damn diskette drive for hours on end and played by turning the wheels by hand, trying to figure a way to make it fly.

I even tried to build a diskette controller for that freebee drive from Finis. Bob Garrow from Intel roughed out a design. I bought the parts. But I, being mainly hardware inept when it comes to debugging the stuff, couldn't get my controller to work.

The absence of a controller for that floppy drive was the only thing between me and a self-hosted compiler for PUM on the Intellec 8/80. And, it drove me nuts that I couldn't get that little drive working.

The disk drive sat in my office at the NPS for a year. I'd just look at it every once in awhile. That didn't seem to make it work any better.

Origins of CP/M

I became tired of spinning that little diskette drive by hand, and I couldn't wait for a controller to magically pop up, so I used my software simulator for the 8080 commissioned by Hank.

So, I built an operting system program using the simulator. I called it CP/M, or a Control Program for Microcomputers, mimicking the name PL/M. For me, CP/M's sole purpose was to support the PL/M language. Nothing else.

Using the simulator, I developed all of the CP/M operating system in PL/M using a minicomputer.

Just like the early days of the i4004, I used no hardware. But, by using the simulation, I knew that CP/M worked. I just couldn't figure out how to make that damn disk drive work. I even made a program editor, the infamous ED that proved true under that simulator.

This was 1974. Out of frustration, I called my good friend from the University of Washington, John Torode. John was a Ph.D. graduate of the Electrical Engineering Department there, and I figured if John couldn't build that controller, no one could.

He did build it. He designed a neat little microcontroller and, after a few months of hardware and software testing, that microcontroller started to work. We loaded my CP/M program from paper tape to the diskette, and "booted" CP/M from the diskette, and up came the prompt

*

This may have been one of the most exciting days of my life, except, of course, when I visited Niagara Falls One Day.

We loaded ED onto the diskette, and I typed

*ED

The ED program editor came up quite well and alive. Ok, so far, so good. I made up a file with ED and put it to disk. The DIR command showed us the file was there, and the TYPE command showed us that what we typed was what we entered using the ED program.

That was in the late afternoon and, feeling lucky, John and I retired to have a Chinese dinner in Pacific Grove. We walked back to the house. and we told one another that this was going to be a "'big thing." (I think this is the third time so far that I heard this expressed. remember the other two?) We drank a jug of not very good red wine and took a well-deserved break.

The Astrology Machine

I only mention the astrology machine incident because it shows how CP/M utility programs were developed for the basic OS. I'm lying. I'm writing about it. because it was a fun project. Ok?

Ben Cooper from San Francisco contacted me through reference by Intel in 1974. Ben wanted to make a "game" machine. Put in a quarter, dial your birthdate, and out comes your horoscope. I'm not into horoscopes, but what the heck, Ben was paying by the hour and I'm not that proud.

Ben is a mousey guy, but an entrepreneur and very easy going. We had good fun working and talking through ideas. He always had his nervous laugh for anyone to accept. He knew quite well about hardware design and enough about software to proceed with building his astrology machine.

Ben liked CP/M, even though it was not a commercial product. And, by that time, I had made a BASIC compiler for CP/M that sort of worked. I despise the BASIC language with a passion, so it is hard for me to admit that I made one. But, I can claim to the good that I never sold it.

Also, by 1974, I had built a real two-diskette drive computer using John Torode's controller that we had replicated several times over. It was not a bad looking prototype, and we had it hooked to my Intellec 8/80 with my CRT that I had nearly paid off. And, good old John Torode, busy with his hardware, was starting a nice business of his own in Oakland, called Digital Microsystems.

I kept the handbuilt "system" in a small converted tool shed at the back of my home in Pacific Grove. Ben would come there from San Francisco and work for days on his Astrology Machine. I wrote programs for him, such as drivers for his little printer, and he used my BASIC to program the astrology algorithms.

Ben worked continuously without break. One sleepy evening he used the CP/M command "del *.*"to get a listing of all his files, which would normally be done with "dir *. *"

Unnecessary to say, but that "del" command didn' t do exactly what he wanted. It deleted all his files, including programs that he'd worked on for days with no backups. This is why, today, you have the choice to "era" files, rather than "del" them. And, this is why you get a prompt "Are You Sure (YIN)?" You can thank Ben for that. Ben, a bit discouraged, crashed at my house for the remainder of the evening and drove back home the next day for a short holiday from the topic of astrology.

He made a few astrology machine prototypes, and put one at San Francisco's Fisherman ·s Wharf. Then, he'd see how people liked it. I guess this would be called a low-budget test marketing scheme.

We watched one night. A young couple, hand-in-hand, walked up and stuck in a quarter. They didn't really bother with setting the birthdate knobs, they just took what happened to be set-in there. The young couple, of course, got someone else 's horoscope. They joined loving hands again and happily walked off, evaluating someone's future written on hardcopy as their own. Because of it, they are probably married with seven children to this day.

Ben Cooper got Remanco, a gaming company in Saratoga, to build 200 astrology machines. I'm not sure how he accomplished this, but Ben was resourceful. I believe they have about 199 left, so if you're interested in one, I'm sure Remanco would appreciate a call.

Ben's astrology machine allowed time and interest in developing CP/M utilies. I taught at NPS by day, and worked on "tools" for CP/M by night. The tools, or "utilities," were programs such as assemblers and debuggers, and programs that managed and manipulated files of programs and data on diskette. These were all necessary to effectively develop applications for the 8080 processor. They were needed to support Ben's game, but useful for any other 8080 developer as well.

The astrology machine was, shall we say, not wildly successful, but later Ben formed a company called Micromation in San Francisco that was. It wasn't until he, and a bunch of other grass-rooters got hit by IBM in the early eighties that his successful business went upside-down. After IBM took his market away with the PC, Ben sold what was left of his company, bought a sailboat, and took an exit stage-left from life. This was typical of hundreds of small companies that felt the brunt of IBM's entry into PCs.

Although he may not know it. his tenacity with that old astrology machine helped me sharpen the CP/M tools. If CP/M wasn 't working right, he'd tell me straight away to fix it.

Jim Warren and DDJ

I worked as a consultant to Signetics through the summer of 1975. Signetics, in competition with Intel. wanted a high level language like PUM. I designed and implemented one and called it PLuS for their 2650. This took all of the summer, and both PLuS and the Signetics 2650 microprocessor bombed.

During my consulting, I met Jim Warren who also consulted there. Jim was instrumental in the early PC cult magazine called Dr. Dobb 's Journal of Computer Calesthentics and Orthodontia. I don 't know what that means, but the Journal appealed to the grass roots of personal computing.

Jim knew of CP/M and, one day at Signetics, suggested that I sell it to the masses. I placed an advertisment in DDJ for CP/M at $25.

Jim was to have me on his TV program that he called Computer Chronicles, which I mentioned before, based at the Public Television Station at the College of San Mateo. Jim left the Chronicles that first year to Stewart Cheifet to host. Stewart then engaged me as co-host, and it turned into a full-time spot for that seven year period. Although an unpaid position, the show gave me weekly connections and exposure to technologies like the "HAL 9000." I have never forgiven Warren for that assignment. Ok ... , I'll again admit, the show was kind of fun .

CHAPTER 6 The Early Hardware and Software Suppliers

Omron, Altair and IMSAI Corporation

In 1975, John Torode and I got a connection to Omron, a CRT terminal manufacturer that specialized in word processing for newspaper editing. John convinced Omron to license CP/M and his controller design for their terminal. We got $25,000 for this, and we split it. This was the biggest pot either of us had won.

Omron built the first real CP/M-based computer hardware product, and, although a bit bulky, it was quite a nice personal machine for the day. We both snagged a couple for our own development. John adapted his controller to Omron's hardware, and I rewrote a diskette driver interface for them.

Meanwhile, during my consulting at Intel that year, we all heard rumors of a new small computer from a company called Altair, headed up by Ed Roberts

Meanwhile, during my consulting at Intel that year, we all heard rumors of a new small computer from a company called Altair, headed up by Ed Roberts. They offered a computer for $500. We all stood around at the Intel lab thinking this one over, because we knew Intel was selling their 8080 chip for $360. Hmmm ... Someone did a deal with someone else to get this to happen. After all, the Intellec 8/80 was selling for ten times that price.

The Altair was a hobby computer that came as a kit from Robert's company in New Mexico. It had a decent enclosure, lights on the front panel, an 8080 processor, but only 256 bytes of memory.

Dave August. a member of our local computer hobby club (called Computer Phreaks United. or CPU), bought one and built it. You programmed that Altair with toggle switches on the front panel. Ok. so that's a bit primitive, but better than the 4004.

Computer clubs were forming elsewhere, with the Palo Alto group being the most prominent. These clubs had members who were often daytime computer engineers from the Silicon Valley area working for firms like AMO and National. These guys were bright enough to build their own computers with no outside help, and they did. Each one was different and unique in its hardware interface.

Then. a new company formed up in San Rafael on the East Bay of Silicon Valley. It was called IMSAI (even though not at all Japanese). IMSAI took Ed's Altair 8080 direction to produce yet another low cost computer. This time headed for the commercial market rather than the hobbyists.

IMSAI products were marketed by Ed Faber, who I had dealt with at Omron, and I'm sure this helped to gain CP/M's entry into IMSAI's organization.

Not only that, but my student, Glenn Ewing was about to leave the Navy and had consulting deals going with IMSAI. IMSAI had promised delivery of a diskette operating system for their customers but hadn't written a line of code for it. Glenn, being my student at NPS, knew about CP/M and proposed that IMSAI use CP/M rather than make their own disk operating system.

Glenn came to my tool shed computer room in 1975, so we could "adapt" CP/M to the IMSAI hardware. What this means is that I would rewrite the parts of CP/M that manage things like diskette controllers and CRTs.

Well. come on, I'd already done this so many times that the tips of my fingers were wearing thin, so I designed a general interface, which I called the BIOS (BASIC 1/0 System) that a good programmer could change on the spot for their hardware. This little BIOS arrangement was the secret to the success of CP/M.

With the BIOS in place, a programmer could make CP/M work with their specialized hardware. With all those hobbyists out there, believe me, there was no shortage of specialized hardware. Glenn and I built a BIOS that afternoon and stuck CP/M on an IMSAI. He demo'd it to Ed Faber and the IMSAI engineers, and they loved it.

I licensed CP/M to IMSAI for $25,000. I was "rich," and IMSAI had their OS that they 'd been promising.

Then, I heard that two guys had made a small BASIC interpreter for the Altair. The two versions were called "4K and 8K BASIC," indicating the size of memory that they used. These two guys were Paul Allen and Bill Gates. who I had run into at Ccubed years before. I was to run into them often again.

And, oh, by the way, Ed Faber from the early days of Omron and IMS AI went on to help form and market today's Computerland.

The Early Days of Microsoft

Understand that the basis for Gates' and Allen's success was in the computer language called BASIC. developed at Dartmouth University in the l 960's. "Waz" wrote a BASIC for his Apple II, and, later, Gates and Allen in competition sold their "Softcard" add-in board for the Apple, with their own BASIC running on my CP/M. Here's how it all started.

Paul Allen and Bill Gates took their BASIC interpreter to the Altair market out of a company they named Microsoft, based in Albuquerque, New Mexico. The location being set, to some degree, by Ed Roberts' factory nearby. Allen and Gates licensed their BASIC language interpreter to Roberts for his Altair.

Bill came to me in Pacific Grove one day in 1977 to discuss his current quandary about relocation of his Microsoft company.

We invited him to stay that night at our home. Dorothy fixed a nice roast chicken dinner, and we had light conversation. Bill told us about the tickets he had received driving at high speed in his Porsche 911 through the main street of Albuquerque. We found a common topic since I. to my misfortune, also enjoy speed of the automotive type that sometimes, but not often, results in an encounter with The Law.

At this time, I was quite friendly with Bill, and we always talked of the "synergism" of our two businesses. But, quite frankly, I was always apprehensive of his business moves, as I found his manner too abrasive and deterministic, although he mostly carried a smile through a discussion of any sort.

Gates is more an opportunist than a technical type and severely opinionated even when the opinion he holds is absurd.

For example, we faced one another in debate over graphics standards at a National Computer Conference in 1979. Bill took the adamant position that NAPLPS would be the wave of the future. Of course, it wasn' t. It's only one example, but don't think for a minute that Gates made it "big time" because of his technical savvy.

Gates and I spent time that day in Monterey driving the Central California coastline while we talked of business possibilities. He wanted to relocate but had not decided where.

We talked of merging our companies in the Pacific Grove area. and we both took that into consideration. Our conversations were friendly, but, for some reason, I have always felt uneasy around Bill. I always kept one hand on my wallet, and the other on my program listings. It was no different that day.

The overriding factor for Bill's decision to relocate was that his family resided in Seattle, with his father being a prominent attorney, and his mother being on the Board of Regents at the University of Washington. His parents lived in a fine brick home at Wyndermere, a posh district just off Lake Washington.

Incidentally, a few months later, Dorothy and I were invited to dinner at Bill's parent's home in Seattle, and I can honestly say that their hospitality was without measure, and we enjoyed their company immensely. They were cordial, and it was apparent that they had been "well-to-do" for many years before.

Bill and Paul made the decision to take their little Microsoft company to Redmond, just a short drive across the "Floating Bridge" from the university campus and Wyndermere, rather than join ranks with DRI at Pacific Grove.

Part of the decision to not join with DRI came from the recognition and acceptance that DRI had in the industry. That recognition limited Bill's growth from within a merger.

The combination of Kildall and Gates could have been a killer-deal in those days. I had the operating systems for the decade to come, and he had the opportunistic approach to garner business. But, our attitudes differed entirely, and that could also have been a disaster. I think we both realized this and simply let the "deal" die.

The West Coast Computer Faire, SSG, and the Electric Pencil

I've talked about Jim Warren. He was a writer and an ex-hippie turned techno, but still with the quirks of his "hippie days." Jim was involved with that Dr. Dobb's Journal of Computer Calisthenics and Orthodontia, where, I mentioned, CP/M was first advertised.

DDJ promoted hobby computing. And, these were the guys who made the foundation for what we, today, think of as the personal computer industry. Jim also formed up the West Coast Computer Faire in 1976, consisting of a collection of small companies that were promoting small computer products.

I was very impressed by Michael Shrayer's "Electric Pencil" program that he presented there. It was the first small computer word processor. Although not elegant because it only used a TV screen with a forty character line in computer fonts, it did show that one need not use "White-Out."

But, the best was Structured Systems Group's display area. Alan Cooper and Keith Parsons made accounting systems using the IMSAI computer and CP/M. I recall telling Dorothy that SSG's was the first really complete application effort for inexpensive computers, and those applications like SSG's would be "a very big thing in the future." (Have we heard this line before?)

Our new company, Digital Research, was represented there. We even shared a booth with SSG. We sold CP/M and the rather technical, but not too inaccurate, documentation that let the hobbyists and budding micro-based commercial computer users access their floppy disks. CP/M was a success.

The next year the West Coast Computer Faire blossomed. Jim Warren took Le Charge de' Affair by roller skating from aisle to aisle, as the show's floor monitor.

In this second year, there were more applications offered to the public. Seymour Rubenstein from defunct IMSAI had coupled up with Rob Barnaby, their best programmer, to sell the word processor called WordMaster. WordMaster was shortlived and reissued as "WordStar." They called their company "MicroPro."

Seymour and Rob had both applied for positions at Digital Research, but I was adamant about avoiding applications that compete with computer makers and Independent Software Vendors, a phrase coined at DRI to describe small companies that make PC programs for specialized markets. These were our customers.

I felt a need to support my manufacturers with an operating system standard and provide a structure they could depend upon. Although this seems like a business position that doesn't max the profit, realize that many of the manufacturers with whom I dealt were personal friends of mine. Quite frankly, I could not, for example, sell an accounting package against Structured Systems Group, and then face Keith and Alan at the next computer conference.

Gates' philosophy was quite different. He had no problem competing with his customers. And, this is where we differed. Monetarily, Bill had the proper approach to get a stack of bucks, and lose a bunch of friends in the meantime. I guess that's ok.

The Softcard

By the year of the 1978 Computer Faire, Gates and Allen had moved their affairs to a small area located within a bank building in Redmond.

Allen had directed the design of the "Microsoft Softcard" (which I must acknowledge as a trademark, and while I'm at it, White-Out is probably a trademark too, oh, and Borland C++ is one, I'm sure, and, say, what have I left out?, Oh, yeah, CP/M is a trademark, and ...)

The Softcard was an add-in board to the Apple IIe. It was an Intel 8080 processor, with interface circuits, to disable that horrible MOS Technology 6502 processor that Steve Wozniak designed into the Apple. The Softcard was to run CP/M and Microsoft's BASIC.

I was contacted by Bill to determine licensing costs. We sat together at this Faire on the vacated second audience floor, overlooking the activity of the packed floor below and talked through the deal.

He got a good one. I wanted a royalty, but Bill wanted a buy-out, and was stuck on that point. 1 sold him 10,000 copies at $2.50 each; the deal was consummated, with my attorney Gerry Davis there taking notes, as lawyers always do.

The Microsoft Softcard was a success, because it gave Apple II users access to a large software base from the CP/M application suppliers, but mostly, for Bill, it gave access to his BASIC language. Bill signed agreements to protect the CP/M design under this licence, as shown in the Appendixes. And, the Softcard was the key to Microsoft's success.

This is the issue. Bill's Microsoft had a BASIC interpreter that would operate with the Apple computer using his Softcard and my CP/M. To Bill's dismay, the Apple platform for application software was controlled by Apple Computers, not Microsoft. That's a wild card for Bill. He "needed" to control the platform for his BASIC, and IBM was to provide him with that.

Battle of the BASICs

Gordon Eubanks is the Chairman of the Board at Semantec today. They have been successful at supplying PC software, such as Q&A and Norton Utilities. I need to write about Gordon, because he was a prime mover and often, but not always, my friend. Most important, Gordon fought a personal battle against Gates and Allens' BASIC language.

I met Gordon when he was a student at NPS. He entered the Computer Science program there to get a master's degree. Gordon was a bright student, but very caustic, vociferous, and downright nasty when he felt his professors were incompetent.

Gordon latched onto me when I was teaching at the NPS, and he was a student in 1974. He asked to do a thesis under my direction, using microprocessors, and I accepted. I proposed two topics. One could be a "word processor," and the other might be a compiler for the BASIC language, which I somewhat discouraged.

But, Gordon took the latter. I gave him my version of BASIC to start with. It was written in PL/M, so he could use the NPS computers to do development. Using this program, he made BASIC-E into a fully working language system for the 8080.

This BASIC-E compiler was Gordon's master's thesis and when he graduated, he went back into the Submarine Service as Engineering Officer onboard a nuclear submarine stationed in the city of Vallejo near IMSAI and IMSAI's new employee, Glenn Ewing, who Gordon knew quite well.

nuclear submarine stationed in the city of Vallejo near IMSAI and IMSAI's new employee, Glenn Ewing, who Gordon knew quite well.

IMSAI wanted a way to program commercial products, such as accounting packages for their new IMSAI 8080 computer. Gordon's thesis project was the right direction, but unfortunately for Gordon, BASIC-E was in the Public Domain. Not only that. I wrote much of it before he had worked on it at all. So, he couldn't sell it to IMSAI.

There was one other problem with Gates ' Basic. BASIC imitates a tiny version of FORTRAN. But, FORTRAN was built for tossing mortars, not computing the National Debt. For example, normally in BASIC or FORTRAN, you might want to print the value of l/3. It comes out .333333333333333 (ad infinitum) depending upon how the computer works. Not only that, internal computations start rounding off. sometimes in the wrong way, and you start to gain or lose pennies here and there. Accountants don't like that.

So, Gordon, while in the Navy, contracted with IMSAI down the street from Vallejo in San Raphael to build a new version of BASIC-E, where all those computations were in decimal (BCD) to make money counting easier to program and to ensure rounding-off didn't happen. Gordon called his compiler "Commercial BASIC." or C-BASIC, and it provided a software tool to make commercial. rather than just hobbyist application programs.

C-BASIC was Gordon's revamp of BASIC-E that he did for his master's thesis, but enough of a revamp that he could sell it. This C-BASIC became the foundation for his company called "Compiler Systems" formed in the Los Angeles basin, run by his frail, but quite clever mother, Mary Eubanks, and controlled by Gordon on his submarine whenever it surfaced.

Gordon became integrally involved in Digital Research in the years that followed. SSG with Alan and Keith in control formed a close alliance with Gordon. SSG developed their accounting software using Gordon's C-BASIC language and, thereby, helped debug the C-BASIC language itself.

Of course, Gates was not happy with Gordon's C-BASIC. This was a threat to him and his plans. I can tell you quite squarely that old Gordon, being a good naval officer hit a direct broadside on Gates with that C-BASIC, because it was very popular with the new ranks of program developers. As a result, Gordon and Bill did not share a love of any sort for one another.

Gordon's C-BASIC was different from Bill's BASIC. C-BASIC was made for commercial products, like SSG's accounting systems, and a host of other products that are alive and well today. Bill's BASIC was for the more casual user. Here's where the two engaged. Bill wanted the entire pie but couldn' t get it because nobody wanted his BASIC for commercial applications, like accounting or inventory. This locked up Bill and Gordon in the BASIC language "tools" marketplace by 1980.

When Gordon left the Navy, he went back to full-time computer work, with his mom holding the fort at his company, Compiler Systems. Shortly thereafter, Gordon joined forces against Gates and company through acquisition by ORI.

This all happened during and after the events at the first "commercial" small computer success, IMSAI, so I'll go back to those days for context.

The Culture at IMSAI

I must admit that IMSAI people were a mixed group in 1978. Seymour Rubenstein, before his departure to form MicroPro, sat in his marketing and sales office with his EST cube, like most of the others there.

Rob Barnaby, on the other hand, was a complete technonerd and lived only to write programs. Rob was a rather tall, lanky person with perpetually unkempt brown hair. He spoke in short sentences that were always direct and to the point. If a question did not relate to computers, Rob did not generally answer.

Rob typed continuously at his IMSAI computer with fingers too large to fit a modern keyboard. But, Rob was always a friendly sort, and I personally give him credit for starting the word processing industry.

While at IMSAI, Rob wrote a program called NED. It meant "New ED." Recall that the ED single line editor started working the same day CP/M did. Hey, in case you have doubts, forget them. I'm not taking credit for the design of NED, Wordstar, or any of those products. Especially not the progenitor, ED, even though under close scrutiny any Court of Law might balk.

Although old ED may have been the progenitor, he may well have only luckily out lasted his lifetime as program "editor."

The only reason ED survived is that it came "free" with CP/M. In ED's defense, however, I can honestly state that there is only one worse line editor that came to the fore later, in the l 980's. It was called Bill's EDLIN supplied by a company from up there in the North Woods.

ED Goes on the Big Screen

Rob Barnaby from IMSAI took my ED design and made it "visual" as well. By visual, I mean that he made ED into a full screen editor that allowed scrolling, paging, and cursor actions, that simplified ED's operation.

Rob wrote that visual NED program while working for IMSAI, but IMSAI went into bankruptcy in 1979, leaving a bunch of software around that the principals apparently didn 't value quite highly.

One was NED. Seymour seized the opportunity and grabbed it before the bankers found it. Then he grabbed up Rob, and Rob finished NED into the WordMaster that I told you about.

Although Rob was clever, he wrote "spaghetti code." This is assembly language programming that may be efficient but could not be understood by another programmer, because it winds in and out of itself. I know. I tried to fix a bug in NED once. I stared at that program for three days and gave up.

Those of you who remember ED may take solace in the events of ED's demise. DRI had an official gathering, organized by Alan Beebe and the Engineering Department in 1984. The attire was black. ED's death was celebrated by all present. I don' t think that was nice, do you? I mean ...

Beginnings of Micropro

After IMSAI's downfall, Seymour and Rob formed MicroPro up in Marin County 's San Ramon, near the George Lucas Ranch, Sear's Point Raceway, and the eternally boring Renaissance Faire.

Seymour and Rob had shown Wordmaster at that West Coast Computer Faire, but then Rob made WordMaster into WordStar, and WordStar was the first successful word processor. Then, Rob was dismissed by the board.

That may have been a fundamental error for MicroPro because, knowing Rob's programming style, I seriously doubt that anyone there could figure out what

he had done. They had to redo the entire WordStar program in the C language, and it took a year or two to get back on-line.

Ok, so Rob wasn 't the world's most generalized coder. He was trying to perform a task with the minimum amount of memory. Those were the constraints of the day. Tight, fast code sells products.

I saw Rob Barnaby five years ago. He was living in a small flat in San Francisco. He gained little personal wealth. But, without Rob's work, MicroPro would simply not exist, and Seymour would be out selling plastic EST cubes.

IMS AI died a quick death in 1979. The bankers sent out notices, and we all came to bid on IMSAI's remains. Computers, terminals, test equipment, chairs and tables.

I found a cabinet of particular interest. It contained all of the CP/M source code that seemed to have a gathering of interested people roaming about it. Our attorney, Gerry Davis, got a court injunction to prevent its sale. That's one thing that Gerry did right

CHAPTER 7 Digital Research

The Early Days of Digital Research

Digital Research started operation in 1976. It was named "Intergalactic Digital Research," because a consultant up in Sausalito held claim to the name "Digital Research." The "Intergalactic" was stuck there by Demi Moore, a creative assistant to our corporate counsel, Gerry Davis. We got the real name back when the consultant went out of business two years after.

The first CP/M Version 1.3 was a cheap piece of software, upped at $70. That was dirt cheap when compared to mainframe software priced in the thousands. Most computer software buffs were astonished. But, CP/M set standards in small computer pricing. And, customers liked it. Well, most liked it. On occasion, we'd get a call in customer service like this. "Any piece of software selling for $70 can't be any good ... bzzzzzzz ... "

God, it would be great if customers still had that attitude. Nowadays, $70 is a highprice. For 70 bucks, the average consumer expects integrated graphics, fax, voice mail, e-mail, data connections to all services, with a two-year no-cost warrantee, and then they make you toss in CD-ROM support with the $1 bonus coupon offer.

The Day Intel Went Flying

There is an old industry rumor. "Gary Kildall came to Intel and offered CP/M for their microcomputer operating system, and Intel rejected it." CP/M became wildly successful in the years that followed, and Intel received the brunt of the "Ha. Ha's."

Like most computer folklore, that's not really how it happened. By 1975, Intel's microcomputer software group had changed control. Hank Smith went to Venrock Investments to become a very successful venture capitalist, and. in fact. was instrumental in funding the two Steves at up-and-coming Apple Computers in Cupertino. Hank Smith. manager of that original Intel microprocessor division later employed me as a consultant to evaluate their investment at Apple Computers.

Bill Davidow took over Hank's position as leader of the Intel microcomputer group. Bill was a good manager but wanted all development to be internal to Intel. I was a wild card for him, and although we had no personal conflict, Bill stopped my consulting service contracts. This was, coincidentally, at the time of CP/M's inception.

Instead, Davidow tasked Ken Burgett, one of those two initial Intel programmers, to build a proprietary operating system. Ken built a good one called ISIS that later became Intel's platform for their own PIJM compiler. I believe it was a good decision by Bill, and a godsend for me and CP/M.

I went high-tailing it back to Pacific Grove and didn't spend much time with Intel after that. Maybe a consulting day or two, until the days of Digital Video Interactive (DVI) in 1990.

Ok, so, I've got this OS that I called CP/M that can be made to fit almost any microcomputer design. More important, I've got the "tool set" for someone to make their own programs without using a mainframe. And, it was priced right at $70.

CP/M and Software Pricing

Let's look at the mentality of the day in 1976. On one of those consulting days in 1976, I sat in a meeting at Intel with marketeer Jim Lally as he discussed pricing.

Says Jim, "Ok, so we sell the Intellec 8/80 for, say, $8.000. and then we sell them a fast paper tape reader for another $2,000. That makes $10,000 off the top. Ok, then we wait until we' ve sold a bunch of these paper tape systems and then introduce the floppy disk drive at $2,500 and ISIS software at another $1,000."

I was dumbfounded. This was a direct attempt to block advancements in our society's technology for the profit of Intel. It was a good lesson for me. I protested. I wasn't listened to, or even considered. But, Jim Lally is now a very successful venture capitalist. I think this is a statement about how certain people manage to get other's assets.

Accumulation of wealth is made by profits of those in possession of goods, and that makes the goods flow more smoothly. Certainly, Intel found that out, and probably mostly from Lally in those days. I never really liked Jim's approach to marketing, but this pricing issue is what made CP/M a success over ISIS and other proprietary designs.

I enlisted the help of my wife Dorothy. I asked that she take care of mailings in response to the DDJ ad for CP/M. The developers had a choice. They could buy Intel's hardware and software development system priced by Lally at $13,500, by the time they tossed their "old" paper tape reader, or they could build their own and buy CP/M at $70. Hmmm ... what would you do if you were a budding scientist?

CP/M was an instant success. The operation in the tool shed moved to Pacific Grove in a small building with an isolated cupola overlooking the normally placid waves of Monterey Bay. Dorothy now went by "Dorothy McEwen," to avoid an association with a "Mom and Pop" operation, and did a fine job of mailing CP/M systems, billing, and invoicing. She contributed in a diligent and directed manner.

But, the success of CP/M was "bang for the buck." It was small, it was fast, it was efficient in operation, it would run on all Intel computers and Zilog Z80s, and it was cheap. No other software product had been priced that way before. Ok, CP/M's price came up to $ I 00 per copy with version 1.4, but no one seemed to care.

Oh, by the way, we did version numbers like this: the first digit was a "major" revision, like I in the 1.3, and the "minor revision" was an "update" like the 3 in 1.3. This worked great.

You charge the manufacturers and customers a "minor" fee to get the minor revision, and then issue a "major" revision, like CP/M 2.0 and charge a major fee. That became the way microcomputer software was labelled. and for that purpose only. See, I did learn something from Jim Lally.

Launching the New DRI

In 1978, Digital Research reached $100,000 per month in sales at about 57% pretax profit, a milestone that allowed our company to move to new quarters in a converted Victorian home at Pacific Grove.

This Victorian spawned a new, growing phase of Digital Research. It was fun. It was exciting. It made new relationships between people. It made a lot of marriages, and they made a bunch of babies. I kind of like that part.

The Victorian home filled with ORI people had spunk. It was alive. It was active. People moving paper and products. People defining the industry through their work.

On my 39th birthday, all of the twenty or so ORI employees got together and held a party for me. That wasn't such an event, because we had parties every Friday afternoon at that Victorian. They gave me roller skates. You know, the kind that look like tennis shoes mounted on a Formula One car.

The party got a little rowdy, which was ok, but I was tasked with getting more champagne. Ok, so I have on my new roller skates, and I head out to the liquor store down the hill about three blocks away. I kept stumbling over those little acorn nuts that drop constantly from trees in Pacific Grove. But, finally, by the grace of God, I made it to that seemingly distant liquor store.

I found temporary haven by hugging a telephone pole near the liquor store for refuge. As I held tight, a guy in a Corvette came by and said, honestly, "hey, man, you're a GREAT skater!" It may have been the best compliment of my life. And, Lord knows how I got that champagne back, but I'm sure it wasn't entirely upon those skates.

Coincidentally, ORI had several "39th" birthday parties for me in the years that followed, and I can tell you, candidly, that ORI knew the meaning of "Party Hardy."

By 1980, DRI had sold millions of copies of CP/M to manufacturers and end-users. We held symposia for thousands of clients at Monterey to train them how to use and adapt CP/M as well as the new MP/M multitasking system and CP/NET. Digital Research was on a roll.

PL/I and New CP/M Versions

Of course, CP/M went through many "versions" like the major and minor ones that I already talked about. In 1978, there was a lot of pressure to make a new one. The pressure came from manufacturers that were using the smaller 5-1/4" disks, like the ones that were introduced with Woz's Apple II. And, our OEMs were pushing for a new standard BIOS for the small disks.

Meanwhile. I had been working intensely on my PUI project, one that took nearly two years to complete. I've talked about PL/M, the computer language that I designed for Intel's microprocessors in 1973, and now I'm talking about PUI.

I did not design PUI. Although the names are similar, these two languages are quite different. My PL/M was a "systems language" for writing tight microprocessor applications, like operating systems and utility programs, such as program editors.

PUI is a language that lets programmers write scientific and data processing applications. It's an entirely different breed of programming language tool.

CP/M version 1.4 was a success in the marketplace, but it really needed a good high-level language. I gave up on PL/M because, even though it was a high-level language, in the sense of today 's "C," it didn't give application programmers the proper operations to make commercially acceptable programs, like office accounting and billing.

We' re talking here about new CP/M versions, right? Not, about programming languages. But, I felt that PUI was necessary to advance the PC platform of applications. And, besides, Tom Rolander was busy on MP/M and CP/Net to support future processors, like Intel's new 16-bit i8086.

Why the Heck PL/I?

CP/M was a stable software item in those heydays of 1978, and it certainly held the title of the Operating System Standard. Ok, CP/M needed an upgrade from version 1.4, which held for a few years, but I felt that greater need to supply a programming language to promote applications under CP/M.

There were not many choices, and still aren ' t. The standard languages were FORTAN. COBOL, Pascal, PUI, and C. Ugggh. None really worked for all microcomputer applications that well.

I got a call in mid-1978 from Dr. Robert Freiburghouse at Data General Corporation near Boston. He was trying to pare down IBM's PL/I. a dinosaur every bit as well done as Disney could have produced.

Please understand that I had to live with that stupid, committee-designed, IBM PUI language on the IBM System/370 for three years by force of conscription. Next to BASIC, it was the worst language ever designed, though running a very close second.

Bob wanted me to attend an ANSI standards committee for a new PUI they called "Subset G," or PUI-G. Bob had known about my design of the PL/M compiler for the Intel microcomputers and figured, mistakenly in my estimation, that I might have something to contribute to the new PUI-G standard.

Freiburghouse's Standards Committee met at the La Playa Hotel at Carmel, California, in mid 1978. I can't say that I was downright nasty at that meeting by telling them that "PUI, by the way, appears as a somewhat overloaded One-Man Band that should, by its character and value, be immediately placed in prominent display at the Smithsonian nearly next to the Reptiles."

Ok, so that was a little nasty. I was particularly unimpressed by the whole affair, but what the heck, the meeting was only down the street from DRI and

Ok, so that was a little hasty. I was particularly unimpressed by the whole affair, but, what the heck, the meeting was only down the street from DRI, and Freiburghouse threw in a free lunch.

But, in listening, I found that Freiburghouse had worked-up a spec ' for a pareddown version of PUI that looked and acted more like Algol and Pascal, with all the business features of COBOL in a clean, complete, and quite usable programming language that might apply to microcomputer applications.

For one thing, PL/1-G adhered more to the rules of the new genre of programming languages, but it kept all the good points, like automatic access to BCD numbers (the kind that accountants like) and good string processing primitives.

Ok, so after complaining about PL/I for a committee session or two, I finally decided I liked Bob's Subset G. I really hate it when I have to admit that I am wrong. Well, at least, Bob got some jollies.

I engaged the PL/I project in that year of 1978 to make "Subset-G" to support our customers under CP/M. I estimated that the project would take Bill Byerly and myself nine months.

Being a truthful person by nature, I must admit that I still hang my head in shame, for that PL/1-G didn't hit the streets for about two years.

"Hey, Ok, so I went a little over schedule. I mean, that can happen to anybody, right? And ... And ... Hey ... my computer was down all week, and I can ' t get that code from Bill that I need before I can work on the next piece for Bill that he keeps asking me for."

"I mean, it's not my problem, it's Bill's. Or, if it's not Bill's it must be that salesman at Intel. I don't remember his name, but he keeps promising that memory board, and I can't load the linker 'til I get it, do you know what I mean? Hey, I even drove up there, but my car broke down in Gilroy and that's gonna cost. say, two grand, and don't you think I can get that Christmas bonus early, 'cause its almost Halloween, you know."

"Yeah, that's it, me and my wife are coming to the DRI party as Russian Cosmonauts. I'm Yuri Gagarin and ... ".

This is how I learned Engineering Management. I've not only heard all the excuses, I can say, quite proudly, that I actually made up most of those excuses myself.

To my defense in tardiness of my PL/I delivery, I make the analogy between building compilers and having babies. To my great fortune, I have not had the opportunity to experience the latter. Here's the analogy.

You can only design and write a few compilers in your lifetime. Otherwise, there are too many of your own creations around to take care of, and all you hear are sounds of crying and screaming when things aren't going right. Besides, although the design concept may be great at the beginning, they take too long to hatch, and meanwhile, you get headaches and can't sleep at night. But, of course, when they are finished. they are always perfect. I've had my last compiler.

But. I would say that this PL/I-80 compiler was quite an elegant design, as it incorporated all of my compiler code optimizing techniques. It made PL/I Subset-G language statements into quite perfect assembly language code for the 8080 to ingest. Hey, cut me some slack and let me brag a bit.

But. the whole project, although it came out properly, was a huge diversion. CP/M needed a revision during that two-year PL/I project. So, the pressures from OEMs and end-users stopped my PL/I efforts for a time to make CP/M version 2.2, and that allowed all those OEMs to make specialized BIOSs to fit other diskette drives that were, unfortunately, mostly incompatible. PL/I-G came out from Digital Research in 1980 and was, by excess, the best compiler built for the Intel chip set.

My interest was in getting a great application tool for the CP/M base through PL/IG. It was an excellent language for programming applications, and assembly language programmers could not do better than the machine code it produced. Many companies took it up, but there was a larger force in action.

Ernst Klenk (born October 14, 1896 in Pfalzgrafenweiler; died December 29, 1971 in Cologne) was a German biochemist.

Klenk's father had a farm and a brewery in the Black Forest. Klenk didn't want to take over his father's brewery and went to high school in Tübingen. After serving as a soldier from 1914 to 1919 in World War I, he studied chemistry at the University of Tübingen. There he received his doctorate in 1923 at the Institute for Physiological Chemistry under the guidance of Percy Brigl (1885–1945). rer. nat. PhD; the topic of the work was the behavior of dipeptides and elastin towards phthalic anhydride. **He then got the position as second assistant to Hans Thierfelder**. After his habilitation, he became a private lecturer there in 1926 and an adjunct professor at the Institute for **Physiological Chemistry** in 1930, which **was headed by Franz Knoop after Thierfelder's death**.

Klenk joined the NSDAP in 1933 [aka the nazi party - https://en.wikipedia.org/wiki/Nazi_Party] and the SA in 1934. [SA - paramilitary - stormtroopers - https://en.wikipedia.org/wiki/Sturmabteilung] [1]

He t**urned down a call to Marburg to succeed Friedrich Kutscher** (1866-1942) and became professor at the University of Cologne in 1936, where he headed the Institute for Physiological Chemistry of the Medical Faculty from 1937 to 1967, which he established. **After the Second World War, he rebuilt the destroyed institute, which had been evacuated to Marburg in 1944. From 1947 to 1948 he was dean of the medical faculty. In 1961/62 he was rector of the University of Cologne, during which time he also helped found the University of Bochum**.

He was Vice President from 1956 to 1959 and President of the Society for Biological Chemistry from 1959 to 1962.

K**lenk was a pioneer in the research of biolipids, their metabolism and related diseases**. He discovered various lipids in the nervous system like the gangliosides (which he named) and various cerebrosides, and he found the cause of Niemann-Pick disease (abnormal accumulation of sphingomyelin) and found the cerebroside accumulated in Gaucher's disease. **He discovered that glycoproteins were cell receptors for certain viruses (myxoviruses)**.

He was co-editor of Hoppe-Seyler's magazine for physiological chemistry.

In 1972 he was posthumously awarded the Otto Warburg Medal, 1964 the first Heinrich Wieland Prize, 1966 the Stouffer Prize [2], he received the Lipid Prize of the American Oil Chemists Society and in 1962 the Norman Medal [3] of the Society for Fat research. He was an honorary member of the American Society of Biological Chemistry and the Society for Physiological Chemistry, a member of the Leopoldina and an honorary member of the Hungarian Society of Neurology. Klenk received the university plaque from the University of Cologne and an honorary doctorate from the Medical Faculty of the University of Cologne.

He had been married to Grete Aldinger since 1937 (who had studied with him in Tübingen) and had three sons, [**Dr. Hans-Dieter Klenk (born 1938)**], Fritz Klenk and Wolfgang Klenk.

physiological chemistry

The son of Johannes Klenk, a brewer, and of Katharina Grossman, Klenk attended gymnasium at Tübingen, and after serving in World War I, he entered the University of Tübingen in 1918 to study chemistry. He took his doctorate in 1923 and worked under Hans Thierfelder, and later Franz Knoop, the discoverer of the β–oxidation of fatty acids. With Thierfelder he wrote a book on the chemistry of the cerebrosides (1930). In his early research under Knoop, Klenk worked on the oxidation of fatty acyl benzene derivatives, thereby laying the foundation for his interest in lipid and fatty acid chemistry. He became associate professor at Tübingen in 1931, and in 1936 he accepted the chair of physiological chemistry at Cologne, a position he held until his retirement in 1967. In 1931 Klenk married Margarete Aldinger, a physician; they had three sons.

https://www.encyclopedia.com/science/dictionaries-thesauruses-pictures-and-press-releases/thierfelder-hans

https://en.wikipedia.org/wiki/Franz_Knoop : 20 September 1875, Shanghai – 2 August 1946, Tübingen) was a German biochemist, most well known for his discovery of the β-oxidation of the fatty acids in 1905.[1][2] ..... Alongside Hans Adolf Krebs and Carl Martius, he clarified the reaction sequence of the citric acid cycle in 1937.[*citation needed*] He determined the structure of histidine and demonstrated that amino acids can be synthesized not only in the plants, but also in animals.[*citation needed*]

Klenk made important contributions to lipid chemistry and more specifically to neurochemistry, a field that had been opened up by Johann Ludwig Wilhelm(John Louis William) Thudichum at the turn of the century. Thudichum summarized his lifework on the sphingolipids of the brain in his *Die chemische Konstitution des Gehirns des Menschen und der Tiere* (1901), Klenk did a considerable amount of work on the cerebrosides. He was the first to isolate nervon, cerebron, and other cerebrosides, and to describe in detail the structures of their fatty acid constituents. In 1929 he demonstrated for the first time the correct chain length (18C) of sphingosine; later he contributed to the elucidation of its structure. He also worked on the composition of polyenolic fatty acids, and he isolated a C_{22} fatty acid that was more highly unsaturated than the wellknown arachidonic acid.

In 1935 Klenk discovered a new class of sphingolipids, the gangliosides. This result came from the investigation of the biochemistry of various neurolipodystrophies, including Niemann-Pick disease, and especially from the study of Tay-Sachs disease, otherwise known as amanrotic idiocy. The latter is a familiar disease of infancy, characterized by a progressive degeneration of nerve cells, eventuating in weakness of the muscles and paralysis. Klenk suggested the name *ganglioside* for the type of glycolipid isolated in this disease, in direct analogy to the already named cerebrosides, and because this kind of glycolipid accumulated in the ganglia cells of the brain in Tay-Sachs disease.

Whereas cerebrosides are localized in white matter, gangliosides were initially thought to be unique to the gray matter of the brain. Because of their high concentration in the gray matter, they were initially regarded as characteristic components of nerve cells. Although gangliosides may be said generally to possess greater complexity than most other sphingolipids, it is now known that they are not exclusively localized either in neurons or in the brain.

In 1941 Klenk isolated neuraminic acid, in the form of the crystallized methylglycoside, from brain gangliosides. Later, with other groups, he went on to elucidate the structure of several gangliosides. He described the acceptor function of neuraminic acid for myxoviruses of the mumps-influenza group and found that neuraminic acid is the determinant group of the MN blood group system.

In the last years of his life, Klenk's major effort was directed to the further purification and elucidation of ganglioside structures. His life's work acted as a strong stimulus to others interested in the structure of sphingolipids and their chemical and enzymatic synthesis and metabolism.

Klenk was a founding member of the editorial board of the *Journal of Neurochemistry* (1957), and served as president of the Deutsche Gesellschaft für Biologische Chemie. Among his honors were the Norman Medal of the Deutsche Gesellschaft für Fettwissenschaft in 1953, the Oil Chemist Award in 1958, the Heinrich Wieland Prize in 1964, the American Oil Chemists Society Award in 1965, the Stouffer Prize in 1966, and the Otto Warburg Medal of the Deutsche Gesellschaft für Biologische Chemie in 1971.

Professor Ernst Klenk

Personal Biography

MY HUSBAND, ERNST KLENK, was born October 14, 1896 in Pfalzgrafenweiler, a village near Freudenstadt in the Black Forest. His father owned a farm and a brewery. He grew up in a happy family and had a brother who was two years older.

When he started elementary school in his home village, the teacher inspired his father to send him to high school and to give him a good education. So he left home at the age of 8. Soon after he lost his brother. Even at that young age he had decided not to take over the brewery but to study, so that his father finally sold this part of his property. At school he was not very fond of languages but was extremely brilliant in mathematics. The schoolboys admired his dangerous experiments with rockets and montgolfieres.

Upon graduation from high school in Tübingen, and the outbreak of World War I, he entered the army as a volunteer. He belonged to the mountaineers and spent 4 difficult years. At least, these years were in beautiful surroundings: the Vogesen, the Dolomites, the Carpates and the mountains of the Balcany. Since that time he has enjoyed the mountains and spends all of his vacations there in summer as well as in winter.

After the end of the war he went to the University in Tübingen to study chemistry. It happened in one of his last terms that he could not get a laboratory space at the Institute of Chemistry, so he moved into the Institute of Physiological Chemistry of which Geheimrat Hans Thierfelder was in charge. The latter was very kind to him and took much interest in his studies. He wrote his thesis under the supervision of Percy Brigl. Before he had finished his thesis work, Thierfelder had made him an assistant. Although he (Klenk) nearly refused in the beginning, Thierfelder encouraged, almost pushed him, to take the academic career. He has always kept a feeling of deep gratefulness and respect towards his master.

After Thierfelder's death he went on working at the same institute under Franz Knoop, the discoverer of β-oxidation of fatty acids. I became acquainted with Ernst Klenk when he tutored me in two chemical courses. We married in 1937 and now have three sons.

Institute in Cologne, having refused to succeed Ft. Kutscher in Marburg. He started with two or three co-workers in a few rooms of the medical clinic. He had just moved into a

In 1936 he was made head of the Physiological Chelnieal building of his own when World War II broke out. The institute was bombed several times. By the end of 1944, it had become impossible to stay longer in Cologne. The institute was evacuated to Marburg" and its suburb.

In the fall of 1945, Klenk returned to Cologne and again started to rebuild his Institute a fourth or fifth time under the greatest of difficulties and with the help of the Marshall Plan. Although the building looked rather poor h'om outside, the team working inside was always especially nice like a family. This family enlarged considerably in the course of the years. The laboratories became too snmll. In 1959 they moved into a fine modern building with very good working facilities.

In 1948 Klenk became dean of the medical faculty and the recipient of an honorary Doctor of Medicine degree by this faculty. In 1962 he was elected president of the University of Cologne. He was awarded the Norman medal of the Deutsche Gesellschaft fiir Fettforschung and the Heinrieh-Wieland-Preis. He is a member of the "Leopoldina" der Deutschen Akademie der Naturforseher and a member in honor of the American Society of Biological Chemistry.

DR. NED. GRETE KLENK, Cologne, Germany

Scientific Achievements

IN 1932 ERNST KLENK began his scientific career under Thierfelder, a former student of Hoppe-Seyler. His initial investigations were concerned with the behavior (retention) of the aromatic fatty aldehydes and of carbohydrates in animals. In his work some information concerning their oxidative degradation was gained. Above all, it was made clear that the oxidation of the methyl group of n-propyl benzene and its higher homologues to a carboxyl group precedes B-oxidation. This finding stimulated his interest in fats and lipids and led him to investigate in detail a glucosamine-containing phosphatide which had previously been reported by Frankel and Kafka in 1920. In an attempt to purify this substance, he came to the conclusion that the isolated phosphatide did not contain hexosamine. He then became interested in the chemical nature of sugar-containing substances in the brain. He succeeded in isolating a cerebroside which had previously been unknown and demonstrated it to consist of a 24-carbon monocarboxylic acid with one double bond, sphingosine, and galaetose. He gave to this cerebroside the name "nervon," and to the monoenoic acid with 24 carbons, "nervonic acid." In subsequent experiments he found

DR. NED. GRETE KLENK, Cologne, Germany

Scientific Achievements

IN 1932 ERNST KLENK began his scientific career under Thierfelder, a former student of Hoppe-Seyler. His initial investigations were concerned with the behavior (retention) of the aromatic fatty aldehydes and of carbohydrates in animals. In his work some information concerning their oxidative degradation was gained. Above all, it was made clear that the oxidation of the methyl group of n-propyl benzene and its higher homologues to a carboxyl group precedes B-oxidation. This finding stimulated his interest in fats and lipids and led him to investigate in detail a glucosamine-containing phosphatide which had previously been reported by Frankel and Kafka in 1920. In an attempt to purify this substance, he came to the conclusion that the isolated phosphatide did not contain hexosamine. He then became interested in the chemical nature of sugar-containing substances in the brain. He succeeded in isolating a cerebroside which had previously been unknown and demonstrated it to consist of a 24-carbon monocarboxylic acid with one double bond, sphingosine, and galaetose. He gave to this cerebroside the name "nervon," and to the monoenoic acid with 24 carbons, "nervonic acid." In subsequent experiments he found

an additional cerebroside containing a 24-C hydroxy acid. This acid was designated as oxynervonic acid and the cerebroside containing this hydroxy was designated as oxynervon. By oxidative degradation of this hydroxy acid, he found it to be a mixture of two isomeric a-oxy-ntetraeosanoenic acids in which the double bond was at either C-15 or C-17. Similarly, cerebronie acid was shown to be an a-oxy-n-tetracosanoic acid.

In addition Ernst Klenk had directed his attention to the sphingosine moiety of the split products from the cerebroside. It was he who gave the first correct experimental formula CI~H.~O..N to sphingosine and thereby made an essential contribution to the elucidation of its structure. By oxidative degradation of triacetylsphingosine, an a, a-dihydroxy-fi-amino-butyric acid derivative was obtained, which after its deacetylation with lead tetra-acetate and subsequent oxidation, gave L (-) serine. Thus the position of the amino group at C-2 of the sphingosine and the configuration around this asymmetric carbon was established, which had also been proved by Carter.

Of Klenk's numerous works on the cerebrosides, one deserving of special mention was the discovery of the substance deposited in Gaucher's disease. This substance was found to be a cerebroside containing glucose instead of galactose. He found that the very high content of phosphatide in the brain, liver and spleen in Nieman-Pick's disease (another lipodosis) is due to the enornmus accumulation of sphingomyelin.

Even in his early days of investigation, Ernst Klenk was very much interested in phosphatides. Attracted by the abundance of acetalphosphatide in the cephalin fractions of the brain, he decided to work on this problem. In the meantime, it had become known that the formula for acetalphosphatide given by Feulgen did not account for a number of experimental findings. The data accumulated from various sources suggested that the substance isolated by Feulgen and Thanhauser is a secondary product derived from the genuine plasnmlogen. No watersoluble phosphate was formed when the phosphatide mixture was treated with acid. After hydrogenation only 30% of the total phosphate could be easily Split off with alkali, and 60-70% of the total phosphate was isolated in the form of chimyl or batylphosphoric acid. These findings led Klenk to propose a formula for the genuine plasmalogen. According to this formula the enol form of the C~ or C~ aldehyde is bound to the primary alcoholic hydroxyl group in an aeetal-like fashion, and the unsaturated fatty acids with 18, 20 and 22 carbons are esterified with the secondary hydroxyl group of glycerol. The chemical constitution of acetalphosphatide is therefore very similar to the classical formula of ethanolamine-cephalin, which explains the close relationship in the physical properties of these two substances. When plasmalogen is hydrolyzed with alkali, the fatty acids are split off. The remainder of the molecule possibly is rearranged to the ether-insoluble acetalphosphatide to which the original formula of Feulgen may be ascribed.

A considerable portion o2 Klenk's work has been concerned with investigation of the structures of highly unsaturated fatty acids found in mammalian organs and in fish oils. From the work of Burr in 1930's a question arose concerning the essential nature of the polyenoic acids such as linoleic and linolenic acids in foods and of the more highly unsaturated C~ tetraenoic acid (arachidonic acid) in liver phosphatides. In the early 1930's, Klenk found a C~ polyenoic acid more highly unsaturated than arachidonic acid. This C~ acid was very similar to "clupanodonic acid" of fish oil and was assumed to be docosapentaenoic acid. He later found eicosapentaenoic and docosahexaenoic acids to be the most highly unsaturated. In his extensive work after 1950, Klenk found it possible to elucidate the structure of a large nmnber of the highly unsaturated fatty acids, primarily by oxidative ozonolysis of the polyenoic acids and by quantitative chromatography of the resulting mono- and dicarboxylic acids. A general principle concerning the structure of these acids was established by this work. It was found that all the double bonds are arranged in a divinyl methane rhythm. They have the chain length of 18, 20, or 22 carbons and belong either to the so-called oleic-, linoleic-, or linolenic- type. Seen from the methyl end the first double bond is situated at the position which corresponds to that of the oleic, linoleic and linolenic acids respectively, i.e., C-9, -6 and -3. Some C~ polyenoic acids of fish oils are the only exceptions to the remarkable regularity mentioned above. The investigations by Klenk on the highly unsaturated acids made clear that the polyenoic acid of the oleic type are present in only small amounts in the mammalian phosphatides and that they are totally absent from fish oils. The principal polyenoic acids of fish oils are of the linolenic type.

By studying the metabolism of these acids he showed that the linoleic-type acids, for example arachidonic acid, arise from linoleic acid, and the linolenic-type acids, e.g., C~o- pentaenoic and C~- hexaenoic acid, arise from linolenic acid. The chains of linoleic and linolenic acids are elongated by "active" acetate addition to the carboxylic end and additional double bonds are introduced in the carboxylicend in a divinyl methane rhythm. On the other hand, all of the oleic-type polyenoic acids seem to be synthesized in the animal body. There exists presumably no fundamental difference among various vertebrates as regards the synthesis of the other polyenoic acids from the so-called essential fatty acids. This has been established by James Mead as well.

The investigations conducted on the lipidoses in the early days of Klenk's scientific career, provided him with another interesting field for research. He found a group of lipids in nerve tissue which had hitherto been unknown. **In 1935 he describel a "substance x" which apparently was closely related to the cerebrosides. This substance appears in larger amounts in nerve tissue in amaurotic infantile idiocy and in Niemann-Pick's disease and in smaller amounts in the normal brain. He designated this substance ganglioside. In 1941 from this glycolipid he was able to isolate by methanolysis a previously unknown crystalline substance. T**his substance was characterized by Klenk as the methylglycoside of a hexosamine-free polyhydroxy-amino acid with 9 or 10 carbon atoms. He called this substance, which yields a red-violet color with Bial's orcinol-ferric chloride-HC1 reagent, "neurarninic acid." Stimulated by the report of Blix of a sfinilar color reaction of submaxillary gland mucin with Bial's reagent , Klenk succeeded in isolating for the first time the N-acetyl derivative of neuraminic acid from mucin, after having been able previously in isolating the crystalline methylglycoside of neuraminie acid from the same material. The N-acetyl fo~ml occurs in blood serum and together with N-glycolyl, N, 0 -di and tri-acetyl derivatives in all mucins of endodermal origin. In addition to his significant contribution to the elucidation of the structure of this very interesting substance he showed that the primary and one of the most important functions of neuraminic acid is to serve as the determinant group of the acceptorsite for the myxovirus of the mumps-influenza group. He has contributed further to the biochemistry of neuraminie acid by showing that the enzymic action of myxovirus is the same as that of the receptor destroying enzyme from the culture filtrate of various bacteria, by showing the role of neuraminidase in virus hemagglutination and panagglutination reactions, and by showing this acid to be the determinant group of the MN blood group system.

In the 1960's Klenk turned his attention once again to the gangliosides. Purification of the gangliosides and determination of their structures by partial hydrolysis, isolation of the oligosaccharides, permethylation, periodate oxidation and by the treatment with neuraminidase, resulted in the conclusion that the gangliosides are a mixture of substances which are very closely related in their chemical compositions. The difference in the fatty acid and sphhigosine moieties are very slight, the main component of the former being stearie acid and that of the latter C~- sphingosine. The C~- sphingosine is replaced by its C~o- holnologue with increasing age. However, there is extensive variation in the carbohydrate portion of the molecule. The carbohydrate sequence in all hexosanline containing brain gangliosides, is glucose- (4-1) galaetose (4-1)- N-acetyl-galaetosamine (3-1)-galaetose with N-acetyl- neuraminic acid in a (3-2)-linkage at first galactose molecule and the glucose molecule is glycosidically bound to sphingosine. A second type of ganglioside which is devoid of the terminal galaetose group exists in only small amounts in the normal brain, but appears in abundance in amaurotic idiocy of Tay-Sachs type. A third ganglioside has two nmlecules of neuraminic acid, one of which lies in the central galactose molecule and the other (3-2) glycosidically bound to the terminal galactose molecule. Of these two neuraminic acids only the latter can be split off with neuraminidase. A fourth type of ganglioside is composed of the same carbohydrate sequence but having two molecules of N-acetyl-neuraminic acid at the first galactose molecule, linked to each other in (8-2) position. An additional molecule of N-acetyl-neuraminic acid may be attached to the 3-position of the second galaetose. The existence in small amounts of a hexosamine-

free ganglioside which contains only glucose, galaetose and N- acetyl-neuraminic acid, was also demonstrated. The configuration of the neutral sugar moiety corresponds to that of lactose. Another hexosaminefree ganglioside consists of 3 molecules of galactose with an N-acetyl-neuraminic acid in position 3 at the central galactose. (Of the extensive works of Ernst Klenk which have been presented in more than 160 publications, only the events of importance could be cited.)

Most of his work has been conducted at the University of Cologne following his appointment as director of the Institute for Physiological Chemistry in 1936. Here his works have been accomplished in cooperation with nearly 100 associates to which group the author of this biography has the honor to belong.

English translation below :

Hans-Dieter Klenk (born June 25, 1938 in Cologne) is a German virologist, recipient of the Robert Koch Medal, university professor and long-time director of the Institute for Virology in Marburg.

Life [edit | Edit source]

Klenk, the son of Ernst Klenk, studied medicine from 1958 to 1963 at the universities of Tübingen, Vienna and Cologne. In 1964 he was awarded the grade summa cum laude Dr. med. PhD. From 1964 to 1967 he completed a postgraduate course in biochemistry at the University of Tübingen. In 1971 he completed his habilitation in virology at the University of Giessen.

While he was working on his habilitation thesis, **he initially worked for three years (1967–1970) at New York's Rockefeller University as a guest investigator in Purnell W. Choppin's laboratory**. [https://en.wikipedia.org/wiki/Purnell_W._Choppin] From 1970 he was research assistant at the Institute for Medical Virology at the University of Giessen, where he worked closely with [**Prof. Rudolf Rott (born 1926)**] for another three years. There he was appointed C3 professor in 1973. He held this professional position for almost twelve years until he was appointed as a C4 professorship and institute director at the Philipps University of Marburg in 1985.

Hans-Dieter Klenk is married and has three adult sons.

Scientific research focus [edit | Edit source]

The focus of the research that Hans-Dieter Klenk and his colleagues have dedicated themselves to are the influenza viruses as well as the Marburg and Ebola viruses. In the work, the structure and reproduction of these viruses were elucidated and important knowledge gained about the mechanisms that are responsible for the pathogenicity of the pathogens and for their transmission from animals to humans. In addition, this work formed the basis for the development of vaccines and antiviral drugs against the Ebola virus and other important pathogens.

2011-jir330.pdf

Assessment of Rodents as Animal Models for Reston Ebolavirus Emmie de Wit,1 Vincent J. Munster,1 Samia A. Metwally,2 and Heinz Feldmann1 1 Laboratory of Virology, Division of Intramural Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Hamilton, Montana; 2 Food and Agriculture Organization Reference Center for Vesicular Diseases, United States Department of Agriculture, Animal and Plant Health Inspection Service, Foreign Animal Disease Diagnostic Laboratory, National Veterinary Service Laboratories, Plum Island Animal Disease Center, Greenport, New York The emergence of Reston ebolavirus (REBOV) in domestic swine in the Philippines has caused a renewed interest in REBOV pathogenicity. Here, the use of different rodent species as animal disease models for REBOV was investigated. BALB/c and STAT12/2 mice, Hartley guinea pigs, and Syrian hamsters were inoculated intraperitoneally with REBOV strain Pennsylvania or Reston08-A. Although virus replication occurred in guinea pigs, hamsters, and STAT12/2 mice, progression to disease was only observed in STAT12/2 mice. Moreover, REBOV Pennsylvania was more pathogenic than REBOV Reston08-A in this model. Thus, STAT12/2 mice may be used for research of REBOV pathogenicity and intervention strategies

[..]

The absence of disease manifestation (in BALB/c mice, Hartley guinea pigs, and Syrian hamsters) and perhaps even replication (in BALB/c mice) makes these animals interesting models as they may resemble the situation in humans, among whom REBOV-induced disease has so far not been observed. The replication of REBOV in guinea pigs and hamsters also creates the possibility of adapting REBOV to these hosts, similar to the adaptation of Zaire ebolavirus to mice and guinea pigs [13, 14], possibly resulting in a disease manifestation similar to that observed in cynomolgus macaques and thus an opportunity to study REBOV disease in guinea pigs or hamsters

KLENK, HANS-DIETER

Institute for Virology, University of Marburg

Hans-Dieter Klenk was born in 1938 in Cologne, Germany. He received his M.D. from the University of Cologne in 1964 and a degree in biochemistry from the University of Tübingen in 1967. **From 1967 to 1970 he was a postdoctoral fellow with Dr. P.W. Choppin at the Rockefeller University in New York**. From 1970 to 1985 he held several positions at the Institute of Virology of the University of Giessen. **From 1985 to 2007 he was Professor of Virology and Head of the Department of Virology of the University of Marburg where he is now Professor emeritus.** His research has focused on the structure and function of enveloped viruses (influenza viruses, paramyxoviruses, filoviruses) with special emphasis on the role of viral glycoproteins and RNA polymerase in the infection process, in pathogenesis and in interspezies transmission. He is author of more than 400 scientific publications. Prof. Klenk was President of the Gesellschaft für Virologie and Chairman of the Virology Division of the International Union of Microbiological Societies. **He serves presently on the International Scientific Board of the Institute of Medical Microbiology of Fudan University, Shanghai, on the Scientific Advisory Board of the Pasteur Institute of the Chinese Academy of Science, Shanghai, on the International Scientific Board of the Guangzhou Institute of Biomedicine and Health of the Chinese Academy of Science, and of the Influenza Pathogenesis and Immunology Research Center, Atlanta**. He is a member of EMBO and of the Deutsche Akademie der Naturforscher, Leopoldina. His awards include: Preis der Deutschen Gesellschaft für Hygiene und Mikrobiologie (1985), Feldberg Lecture, London (1987), Aronson-Preis, Berlin (1989), Shipley Lecture, Harvard Medical School (2003), Robert-Koch-Medal in Gold, Berlin (2006), Ernst-Jung-Medal in Gold, Hamburg (2008), Emil von Behring-Preis, Marburg (2010).

NOTES - "University of Giessen" is only 5 miles from Marburg

https://en.wikipedia.org/wiki/Purnell_W._Choppin

Purnell W. Choppin is an American virologist. He served on the faculty of Rockefeller University for nearly thirty years, becoming the Leon Hess Professor of Virology. He moved to the Howard Hughes Medical Institute in 1985, became the president of the institute in 1987, and retired in 1999, succeeded by Thomas Cech. He is currently the chair of the Scientific Advisory Board at the Center for the Study of Hepatitis C, supported by a university consortium consisting of Rockefeller, Weill Cornell Medical College, and New York-Presbyterian Hospital.[1][2]

...

In 1985 Choppin moved from his position as the Leon Hess Professor of Virology at Rockefeller to the Howard Hughes Medical Institute, where he served as vice president and chief scientific officer. He assumed the presidency in 1987, succeeding Donald Fredrickson.[4]

https://en.wikipedia.org/wiki/Rockefeller_University

The Rockefeller University was founded in June 1901 as **The Rockefeller Institute for Medical Research**—often called simply **The Rockefeller Institute**—by John D. Rockefeller, who had founded the University of Chicago in 1889, upon advice by his adviser **Frederick T. Gates**[1] and action taken in March 1901 by his son, John D. Rockefeller Jr.[7] Greatly elevating the prestige of American science and medicine, it was America's first biomedical institute, like France's Pasteur Institute (1888) and Germany's Robert Koch Institute (1891).[1] The Rockefeller Foundation, a philanthropic organization, founded in 1913, is a separate entity, but had close connections mediated by prominent figures holding dual positions.[8]

,...

Notable individuals

Notable figures to emerge from the institution include Alexis Carrel, Peyton Rous, Hideyo Noguchi, Thomas Milton Rivers, **Richard Shope,** Thomas Francis Jr, Oswald T. Avery, Rebecca Lancefield, Wendell Meredith Stanley, René Dubos, Ashton Carter, and Cornelius P. Rhoads. Others attained eminence before being drawn to the university. **Joshua Lederberg,** who won the Nobel Prize in Physiology or Medicine in 1958, served as president of the university from 1978 to 1990.[12] Paul Nurse, who won the Nobel Prize in Physiology or Medicine in 2001, was president from 2003 to 2010.[13] (Before Nurse's tenure, Thomas Sakmar was acting-president from 2002.[14]) In all, as of October 2020, 38 Nobel Prize recipients have been associated with the University. In the mid-1970s, the University attracted a few prominent academicians in the humanities, such as Saul Kripke.

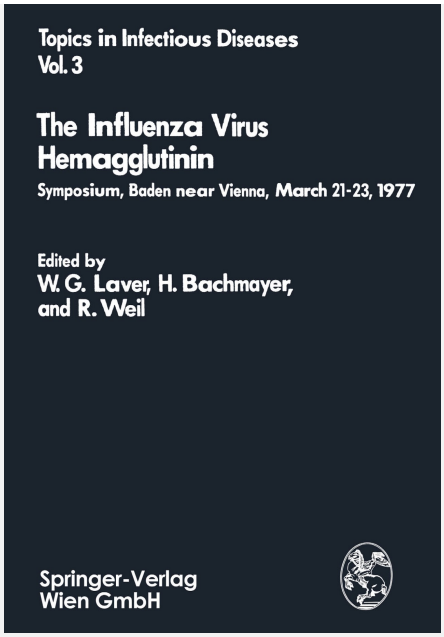
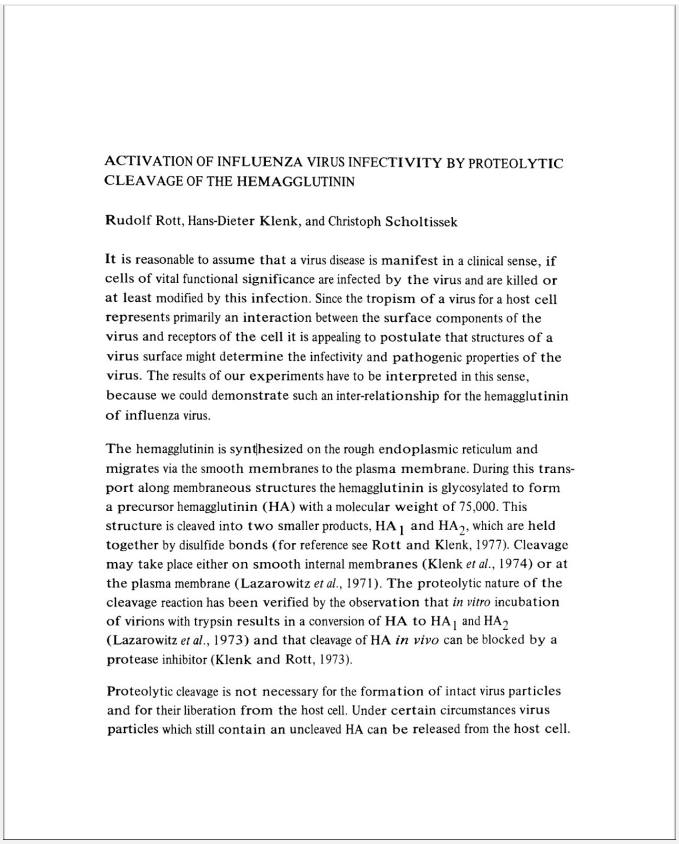
Abstract

"It is reasonable to assume that a virus disease is manifest in a clinical sense, if cells of vital functional significance are infected by the virus and are killed or at least modified by this infection. Since the tropism of a virus for a host cell represents primarily an interaction between the surface components of the virus and receptors of the cell it is appealing to postulate that structures of a virus surface might determine the infectivity and pathogenic properties of the virus. The results of our experiments have to be interpreted in this sense, because we could demonstrate such an inter-relationship for the hemagglutinin of influenza virus."



[HI002J][GDrive]



ACTIVATION OF INFLUENZA VIRUS INFECTIVITY BY PROTEOLYTIC CLEAVAGE OF THE HEMAGGLUTININ

Rudolf Rott, Hans-Dieter Klenk, and Christoph Scholtissek

It is reasonable to assume that a virus disease is manifest in a clinical sense, if cells of vital functional significance are infected by the virus and are killed or at least modified by this infection. Since the tropism of a virus for a host cell represents primarily an interaction between the surface components of the virus and receptors of the cell it is appealing to postulate that structures of a virus surface might determine the infectivity and pathogenic properties of the virus. The results of our experiments have to be interpreted in this sense, because we could demonstrate such an inter-relationship for the hemagglutinin of influenza virus.

The hemagglutinin is synthesized on the rough endoplasmic reticulum and migrates via the smooth membranes to the plasma membrane. During this transport along membraneous structures the hemagglutinin is glycosylated to form a precursor hemagglutinin (HA) with a molecular weight of 75,000. This structure is cleaved into two smaller products, HA_1 and HA_2, which are held together by disulfide bonds (for reference see Rott and Klenk, 1977). Cleavage may take place either on smooth internal membranes (Klenk *et al.*, 1974) or at the plasma membrane (Lazarowitz *et al.*, 1971). The proteolytic nature of the cleavage reaction has been verified by the observation that *in vitro* incubation of virions with trypsin results in a conversion of HA to HA_1 and HA_2 (Lazarowitz *et al.*, 1973) and that cleavage of HA *in vivo* can be blocked by a protease inhibitor (Klenk and Rott, 1973).

Proteolytic cleavage is not necessary for the formation of intact virus particles and for their liberation from the host cell. Under certain circumstances virus particles which still contain an uncleaved HA can be released from the host cell.

[HI002K][GDrive]

ACTIVATION OF INFLUENZA VIRUS INFECTIVITY BY PROTEOLYTIC CLEAVAGE OF THE HEMAGGLUTININ

It is reasonable to assume that a virus disease is manifest in a clinical sense, if cells of vital functional significance are infected by the virus and are killed or at least modified by this infection. Since the tropism of a virus for a host cell represents primarily an interaction between the surface components of the virus and receptors of the cell it is appealing to postulate that structures of a virus surface might determine the infectivity and pathogenic properties of the virus. The results of our experiments have to be interpreted in this sense, because we could demonstrate such an inter-relationship for the hemagglutinin of influenza virus.

The hemagglutinin is synthesized on the rough endoplasmic reticulum and migrates via the smooth membranes to the plasma membrane. During this transport along membraneous structures the hemagglutinin is glycosylated to form a precursor hemagglutinin (HA) with a molecular weight of 75,000. This structure is cleaved into two smaller products, HA 1 and HA2, which are held together by disulfide bonds (for reference see Rott and Klenk, 1977). Cleavage may take place either on smooth internal membranes (Klenk eta!., 1974) or at the plasma membrane (Lazarowitz eta!., 1971). The proteolytic nature of the cleavage reaction has been verified by the observation that in vitro incubation of virions with trypsin results in a conversion of HA to HA 1 and HA2 (Lazarowitz et at., 1973) and that cleavage of HA in vivo can be blocked by a protease inhibitor (Klenk and Rott, 1973).

Proteolytic cleavage is not necessary for the formation of intact virus particles and for their liberation from the host cell. Under certain circumstances virus particles which still contain an uncleaved HA can be released from the host cell.

Particles with a precursor HA or the hemagglutinin composed of the cleavage products HA 1 and HA2 are equally capable of a hemagglutination reaction, and in both cases the hemagglutination can be inhibited by specific antisera. This means that the reactive antigenic determinant is not significantly modified by proteolytic cleavage. The same holds true for the interaction of the hemagglutinin with the host cell. In all systems tested cleavage was not necessary to establish adsorption of virus particles to neuraminic acid containing receptors at the cell surface. A cleaved HA is necessary, however, for the infectious process to proceed further (Klenk eta/., 1975; Lazarowitz and Choppin, 1975).

Infection of embryonated chicken eggs or cells derived from the chorioallantoic membrane of the chick embryo with influenza strains of human and animal origin results in the formation of infectious progeny virus. Attempts to grow infectious viruses in chick fibroblasts are only successful with strains which possess the hema.gglutinin of fowl plague virus (FPV), while all others have only a negligible infectivity. Analyses in polyacrylamide gels show a direct correlation between infectivity and the structure of the hemagglutinin. Only particles with a cleaved HA are infectious. A successful cleavage of HA which corresponds to productive conditions in vivo can be carried out in vitro by treating the inactive virus particles with trypsin. Such a treatment also activates infectivity (Table 1).

A productive infection of cells in which infectious virus is normally not formed is attained if trypsin is added to the culture medium. This becomes particularly evident, if cells are infected under single and multiple cycle conditions with a multiplicity of infection ranging from 30 to 0.003 PFU/cell (Figure 1). Growth curves of FPV which is synthesized in such cells as infectious particles with cleaved HA are identical irrespective of the presence of trypsin. On the other hand a clear requirement for the enzyme is observed in the case of virus N.

When trypsin is present in the medium, replication is similar to that of FPV. In the absence of trypsin, however, newly synthesized non-infectious virus is only demonstrable under single cycle conditions. Under multiple cycle conditions virus production progressively decreases as the multiplicity of infection is reduced. This phenomenon also explains plaque formation by such strains which are normally non-plaque producers in chick fibroblasts in the presence of trypsin (Figure 2).

Whether a proteolytic cleavage is possible in a given host cell is determined primarily by the individual structural characteristics of the HA rather than by

the activation of cellular proteases by the infecting virus. This could be demonstrated by double infection of chicken fibroblasts with FPV and virus N, which are produced in highly infectious form or with reduced infectivity, respectively.

Since HA 1 and HA 2 have different electrophoretic mobilities in FPV and virus N, it was possible to determine the origin of the cleaved HA in the mixed virus population by coelectrophoresis with homogeneous preparations of each virus.

The glycoprotein pattern of the progeny virus is shown in Figure 3. The results show clearly that after double infection FPV does not induce cleavage of the hemagglutinin glycoprotein of virus N. Biological tests confirm our previous observation that virus N requires try;>sin to undergo multiple cycle replication in chick fibroblasts, whereas FPV can do so in the absence of the enzyme. In doubly infected cells only FPV-specific hemagglutinin is formed if trypsin is absent. In the presence of trypsin, however, hemagglutinin of both strains can be detected (Table 2).

[...]

Comparisons of the nuclear magnetic resonance (NMR) spectra of chicken fibroblasts exposed to virus N with either cleaved or uncleaved HA are being carried out in our laboratory by C. Nicolau and H-D. Klenk. The results suggest that the hemagglutinin is in fact involved in the penetration process. These studies indicate that virus N with cleaved HA induces an alteration in the fluidity of the lipid bilayer of the plasma membrane, whereas virus N containing uncleaved HA does not. Simitar but more distinct fluidity changes have been observed when Newcastle disease virus containing a biologically active fusion glycoprotein has been compared to virus containing an inactive F glycoprotein.

This could mean that the mechanisms of penetration process resemble each other in both cases and that the function, which is exerted by the F glycoprotein of paramyxoviruses must be attributed to the hemagglutinin of influenza viruses.

Since a hemagglutinin composed of the cleavage products of HA 1 and HA2 is indispensable for the formation of infectious virus particles, only those conditions which have been def"med in our in vitro studies can predispose to a pathological situation in the host organism. In contrast to former conclusions from others it is now clear, however, that viral glycoproteins alone do not determine pathogenicity of influenza viruses. This could be convincingly deduced from a series of experiments, where recombinants of fowl plague virus were compared in vitro and in vivo (Rott et al., 1976). In these experiments there was no correlation between the presence of cleaved glycoproteins and the pathogenicity of the virus. Furthermore, using the same parent recombinants for double infection, the progeny back recombinants were only infrequently pathogenic for chicken, although they carried both surface antigens of the highly pathogenic FPV (Table 5). The results of these experiments show clearly that the pathogenicity of influenza virus depends on more than one gene. This conclusion was underlined by experiments (Table 6) where FPV recombinants were employed which carried a particular defined gene from other influenza viruses (Scholtissek et al., 1977). Here again it became clear that the FPV derived HA cannot induce the disease in the natural host, but a certain gene constellation is necessary to make up a pathogenic virus. Full reconstitution of pathogenicity to levels of the wild type FPV largely depends on the parent strain being used for the gene exchange and the particular gene which is carried 0'Ä~er. This means again that there is no individual gene coding for pathogenicity and that the HA gene is not a 'virulence' gene by itself.

At the present time we cannot list the optimal gene constellation to make up a pathogenic virus and we are not in a position yet to define the particular contribution made by the individual genes which might finally result in the complex phenomenon of pathogenicity.

Profile: Gary Kobinger — "My goal became to prevent death"

Véronique Morin

Gary Kobinger toiled in obscurity until a couple of years ago when, during the Ebola crisis, the chief of special pathogens at the Public Health Agency of Canada's (PHAC) microbiology laboratory in Winnipeg vaulted to the rank of international hero.

In the midst of the epidemic that claimed more than 11 000 lives, he and his team announced that they had developed both an effective treatment — a drug called ZMapp — and a vaccine against the lethal virus.

Although both are still in clinical assessment, these discoveries came as heartening news to a world gripped by fear of a hemorrhagic fever that, on average, kills half of those who contract it. The twin breakthroughs received attention from media, scientists and public health authorities across the globe, and led to Kobinger being nominated for such honours as Radio-Canada's scientist of the year.

Dr. Xiangguo Qiu of PHAC, who is first author on most of the publications related to ZMapp, says Kobinger's support was exceptional. "He immediately saw the potential for this treatment," said Qui. "We established a plan together. He is very quick and knowledgeable. It is great to work with him. Without him the treatment we developed would have never seen the light."

The praise and media attention has not distracted Kobinger from his work. He is quick to give credit to his team, and to point out that the Ebola breakthroughs were part of a much wider — and longer — battle against highly infectious diseases.

"My team and I are working on a MERS [Middle East respiratory syndrome] vaccine, currently tested in a phase one clinical trial," he said in an interview from his Winnipeg laboratory. "We also have a vaccine against Zika that could be ready as early as this summer."

With the mosquito-borne Zika virus spreading from Brazil to other countries and potentially causing increases in rates of both microcephaly in newborns and Guillain-Barré syndrome in adults, Kobinger fully understands there is no time to waste. Thankfully, he will not be starting from scratch.

"It may sound extraordinary, but we have known and developed this [method] for over 10 years. So what is in fact extraordinary is that it took an epidemic to receive the attention our work deserved," he said. "We were working in the shadows for years and years."

It would be hard to imagine a work environment less glamorous, or more dangerous. He often works alone in this maximum-containment facility — Canada's only level-4 biosafety containment laboratory — wearing what looks like a blue spacesuit, complete with a hood and gloves. Most of his days end with a

only level-4 biosafety containment laboratory — wearing what looks like a blue spacesuit, complete with a hood and gloves. Most of his days end with a chemical shower. Yet it is precisely these conditions that have helped Kobinger to attain understanding of the complex mechanisms that could protect human cells from highly infectious and deadly viruses.

“It is so quiet in a level-4 lab,” he said. “The air and temperature are controlled, which allows me to reach an intense level of concentration and focus on my work.”

From the perfect ambient temperature and controlled conditions of his lab, his research took him to the heat and squalor at the heart of the Ebola outbreak. His desire to stop infectious disease in its tracks was fanned by what he witnessed there.

“You never forget the expression of fear imprinted on the face of someone who has died of Ebola,” he said.

Over the course of four trips to Africa between 2007 and 2014, he was instrumental in implementing safety protocols as cochair of the World Health Organization’s (WHO) Emerging and Dangerous Pathogens Laboratory Network. With the danger of infection all around them, he and his team were careful to follow all protocols. “I’m motivated by the fact that we can prevent deaths. I have a wife and children, and of course I was thinking about them when I saw women and children dying of Ebola in front of us.”

It was particularly tough to watch death strike when he knew he had a potential cure, as well as a vaccine, at his lab back in Canada. “The hardest thing is administrative and bureaucratic delays which slow us down. Delays make me impatient.”

Kobinger’s sense of urgency about his mission is palpable, but the path that led the Quebec City–born scientist to the Winnipeg lab and to Africa’s shores was not always so direct. The self-described “medical school dropout” spent a year planting trees and travelling before finding his true calling.

“He came back very sick from a trip to India,” recounts his mother, Nicole Kobinger. “I think that this was a determinant for him. One day, after several months of lying ill in bed, he got up and decided to return to university.”

Kobinger’s brush with mortality gave him a sense of purpose. “I realized there was a great need to immunize and protect people from emerging infectious diseases. I became fascinated with viruses and I was convinced we could help people. My goal became to prevent death.”

He pursued his studies with those he considered the best in his field. His doctoral work was with Éric Cohen of Université de Montréal’s Institut de recherches cliniques de Montréal, who was known for his research into retroviruses such as HIV. Then from 1999 to 2004, he did postdoctoral training under James M. Wilson’s supervision at the University of Pennsylvania in Philadelphia. “He joined my lab at a time when [there was] a collection of incredibly ambitious and aggressive post-doc cohorts,” said Wilson. “He was part of that exceptional and superior class of researcher that came through.” Wilson credits Kobinger with conducting extremely challenging experiments using bits of the HIV virus and pseudotyping them with bits of the Ebola virus, at a time when bio-threats were heightened.

“After 9/11, and biosecurity heightened, it became very hard to gain access to one of those labs. Gary was very persistent and impatient with the bureaucratic delays, but not in a reckless way. I admire that in him,” said Wilson. “He is an amazing human being; the type that I have rarely encountered. What is so amazing about him is that he is one of the very rare people who are extremely smart, pursuing ambitious goals while abiding by very high levels of principles, and with great generosity. I mean, he would give his shirt off [his back]. What he did in Africa was selfless. It is very rare in our world, where competition is fierce and ruthless, to encounter that level of selflessness and integrity in one human being.”

Vaccines usually take at least 10 years to develop, but Kobinger and his PHAC team claim to have created what he calls a “template” — or recipe — that applies to several types of vaccines, including one tested against Ebola. This type of vaccine acts on several fronts to trigger an appropriate immune response.

“When you look at the structure of the wormlike Ebola virus under the microscope, you see its surface is peppered with glycoproteins,” he said. These proteins, which form the envelope of many other viruses, bind onto human cells and act as keys, opening a target cell and allowing the virus to penetrate and infect it. By using glycoproteins in combination with features of other infectious agents, this new type of vaccine triggers an immune reaction that has produced promising results in the recent initial human tests.

Kobinger leaves PHAC in June to head Laval University’s Infectious Disease Research Centre in his hometown of Quebec City. “We will miss him greatly, says Qiu. “We love him here, and we wish him luck.” Kobinger may be moving across the country, but his goal remains the same: preventing death.

Leading vaccine developer walks out on federal vaccine task

force

Gary Kobinger, who worked with the Winnipeg team that developed a successful Ebola vaccine, has resigned from a federal task force of high-level vaccine experts, pleading for more transparency in the battle against COVID-19.

With conspiracy theorists interpreting the current low death rate from COVID-19 as a sign the pandemic is over, even as the number of cases continues to rise, experts and political leaders need to be more forthright, Kobinger believes.

His warning comes as public health authorities say Canada could be drifting into a second wave of the pandemic.

“The first step is transparency,” Kobinger said in a telephone interview Monday.

He would like to have journalists specializing in health sitting in on the deliberations of the task force, with a link allowing anyone in Canada to tune it as well.

“Everybody should be able to call in.”

The World Health Organization allows journalists with health expertise to sit in on its meetings, Kobinger said.

Kobinger also proposed that members of Canada’s task force publicly declare their conflicts of interest to put to rest potential suspicions they are not working in the public interest, and are not influenced by corporate or other connections.

On Monday, Conservative health critic Michelle Rempel Garner and public services and procurement critic Pierre Paul-Hus blamed the Trudeau government for lacking transparency in their deliberations over vaccines.

“Canada’s Conservatives will continue to press for these answers and demand to see a plan,” she said in a statement.

“Canadians’ health needs to drive vaccine decisions, not the bottom-line of pharmaceutical companies. It is extremely disturbing to see reports that members of Justin Trudeau’s vaccine task force stand to make money off of the outcome of procurement decisions.”

Canada’s National Research Council announced the creation of the task force, made up of 18 top-of-their-field experts from academia and vaccine producers, in August.

Kobinger noted that while task force members were required to sign a conflict of interest and confidentiality agreement, those conflicts of interest were not made public.

“I don’t want my name involved in this,” he said.

Joanne Langley, one of two task force co-chairs, is listed as a Dalhousie University professor of pediatrics, community health and epidemiology and head of infectious diseases at the IWK Health Care Centre in Halifax.

But Kobinger said Langley also receives funds from Novavax, Pfizer and Johnson & Johnson’s Janssen unit. On Aug. 31, federal Procurement Minister Anita Anand announced Ottawa would buy up to 76 million vaccine doses from Novavax in Maryland, as many as 38 million doses from Janssen.

Earlier that month, Canada ordered 20 million vaccine doses from Pfizer and 56 million doses from Moderna. It was also in talks with AstraZeneca.

Langley was also a principal investigator for a vaccine prospect being developed by China-based CanSino Biologics.

Kobinger wonders what happened to the federal funding Ottawa committed to that project, for testing centred in Halifax. It fell apart after China’s customs refused to allow CanSino’s candidate to ship to Canada for months.

READ MORE: Canada-bound vaccine blocked by China's customs was created with Canadian tech

Two of the prospective vaccines Canada is considering, developed by Pfizer and Moderna, are based on RNA, ribonucleic acid.

This is a new approach, which Kobinger said is interesting, but choosing two RNA vaccines is "taking a big risk."

Kobinger is working on his own vaccine project and is doing testing on vaccines developed by Medicago in Quebec City, as well as Inovio in Pennsylvania, which is developing a DNA (deoxyribonucleic acid) vaccine.

Medicago's plant-based vaccine uses virus-like particles, a technology employed in the successful HPV vaccine.

"That would be the first candidate I would look at," Kobinger said.

There is another Canadian vaccine project receiving federal funding at the University of Saskatchewan's VIDO-InterVac project.

The first priority in the task force's mandate calls for, "Prioritizing vaccine projects seeking support for activities in Canada."

Kobinger interprets this as meaning having vaccines produced in Montreal at the National Research Council's Biotechnology Research Institute, better known as NRC-BRI, where Ottawa has committed $125 million.

But he noted that Medicago now is the only vaccine developer in Canada with its own manufacturing facilities, and the capacity on its own to do testing through phases one to three.

Kobinger said he has been inundated with emails from others in the vaccine sector since his resignation from the task force became public. Some are nasty, but "an amazing number" are congratulating him.

"Some of my colleagues are really mad at me," he said.

Kobinger has also worked with the Singapore government in fighting COVID-19. Singapore is one of the East Asian countries that have controlled COVID-19 and have low death tolls. Kobinger said the reason Singapore has done so well is that they were prepared for a pandemic "five years ago," with the needed personal protective equipment, epidemiologists and other health experts ready to act.

Canada was not as well prepared, but Kobinger still has praise for Canada's chief public health officer Dr. Theresa Tam, who he says is doing "an incredible job."

Kobinger believes Canada, in addition to beating the current virus, has to prepare for the next pandemic.

"I've never seen Canada spending so much on science," he said.

But the mixed messages on masks, with public health authorities early-on advising against their use, now insisting that masks be worn, has confused people.

Prescribing transparency, Kobinger said public health should have said then, "We don't have enough masks."

Another critique is that in March, when there was awareness the virus was coming, Canadians travelled abroad during spring break, bringing the virus home with them.

Kobinger questions whether political leaders should be involved in the process, suggesting that a health authority, free of political considerations, might do a better job communicating the dangers and the prescriptions to defeat COVID-19 and future pandemics.

CORRECTION: A previous version of this story said Gary Kobinger led the Winnipeg team that developed a successful Ebola vaccine, instead of worked with the team.

PUBLIC RELEASE: 18-MAY-2017

Canadian researcher wins grant to explore promising HIV vaccine candidate

Canadian Institutes of Health Research funds Gary Kobinger to develop HIV vaccine in partnership with IAVI

INTERNATIONAL AIDS VACCINE INITIATIVE

SHARE

PRINT E-MAIL

The Canadian Institutes of Health Research (CIHR) has awarded a new CA$3.99 million grant to Gary Kobinger of Université Laval for work on a vaccine to prevent HIV infection.

This three-year grant supports a scientific collaboration between Kobinger and the Design and Development Lab, a state-of-the-art research facility in Brooklyn, New York, operated by the International AIDS Vaccine Initiative (IAVI). Led by Kobinger and IAVI's Chris Parks, the respective Canadian and U.S. research teams aim to improve upon a promising HIV vaccine candidate designed by Parks, with the goal of advancing the candidate to clinical testing in human volunteers.

"We are encouraged by this support of Gary Kobinger's work and the prospects of his collaboration with IAVI's Design and Development Lab," said Mark Feinberg, IAVI CEO. "The innovative work of the Kobinger lab provides a great illustration of how creative and insightful science can advance the global response to emerging infectious diseases, and exemplifies ways in which the benefits of research progress in one disease area can be translated to another, in this case, from an understanding of how to develop an effective Ebola vaccine to the ongoing search for an AIDS vaccine."

Using a modified animal virus called Vesicular Stomatitis Virus (VSV) that does not cause disease in humans, the IAVI vaccine candidate delivers copies of a protein taken from HIV's surface. Once inside the body, the protein stimulates protective immune defenses against HIV infection. Studies in animals to date have yielded encouraging results.

Kobinger's team will further modify the IAVI candidate vaccine for greater efficacy and clinical testing. An expert in the Ebola virus, Kobinger helped develop the Ebola (rVSV-ZEBOV) vaccine, which to date has proven the most effective at preventing Ebola infection, and which also uses a VSV backbone.

"While there is still much work to be done, progress is being made towards finding a vaccine that will protect and eventually eliminate HIV/AIDS, one of the most serious health threats of our time," said Marc Ouellette, Scientific Director, Institute of Infection and Immunity, CIHR.

In 2016, more than 2 million people were newly infected with HIV around the world. Though antiretroviral treatment has prolonged life for millions, scientists concur that discovering a vaccine against HIV is the only way to end the AIDS epidemic. By combining their expertise, CIHR and IAVI hope to advance the field of HIV vaccine discovery and to build a more efficient vaccine-development model that can potentially be replicated in other disease areas.

Gary Kobinger is world-renowned for his work on the Ebola vaccine and treatment of those affected by the disease. More recently, while Chief of Special Pathogens with the Public Health Agency of Canada's microbiology laboratory in Winnipeg, Kobinger garnered international attention for his efforts to develop a treatment and vaccine against the Zika virus.

Canadian company announces possible coronavirus vaccine candidate

March 13, 2020 10:08 PM in News
Source: WBRZ
By: WBRZ Staff

CANADA- Medicago, a Quebec-based biopharmaceutical company, said it has produced a virus-like particle of the novel coronavirus, a first step to producing a vaccine.

The isolated particle will now undergo pre-clinical safety and efficacy.

Medicago said it could begin human trials as soon as July or August if approved by Health Canada and other agencies.

If the vaccine is successful, it could be available to the wider public by November 2021, CEO Bruce Clark said.

“These timelines are heavily reliant on what will give the regulators enough comfort to say this product is ready to go into human testing and then, secondly, for use in the broader public,” he said. “Our best guess right now is 18 months.”

Within just 20 days of obtaining the gene of the virus, Medicago researchers were able to produce a candidate vaccine, Clark said.

If given the green light, they could produce as many as 10 million doses per month out of their plant in North Carolina. The company currently has the resources to create about two million doses per month out of its plant in Quebec, according to Clark.

The biopharmaceutical company said they used a plant-based platform to grow vaccine proteins rather than chicken embryos, allowing for them to make the vaccine candidate quickly.

“We have a [seasonal flu vaccine] that is currently under review with Health Canada, and the [technology] we are using for this COVID vaccine is exactly the same, which has proven to be efficacious,” Clark explained.

The company’s ability to grow virus-like particles in plants has helped it produce vaccines in the past against influenza, including a vaccine candidate against H1N1 in 2009, Canada Research Chair Dawn Bowdish said.

“A virus-like particle looks like the outside of a virus but doesn’t have any of the genetic material on the inside,” said Bowdish, who also sits on the scientific advisory board of Medicago. “It doesn’t cause infection but looks really similar from your immune system’s perspective.”

Medical researchers around the world continue to race to develop a vaccine for COVID-19.

Medicago is also working to develop antibodies against SARS-CoV-2, the pathogen that causes COVID-19, in collaboration with Dr. Gary Kobinger, who helped develop the vaccine and treatment for Ebola.

Bowdish warns that most vaccine trials fail and in 17 years there was never a vaccine fully developed for the SARS outbreak.

"It’s unlikely there will be a miracle drug,” she said. “But Canada has had some incredible successes creating vaccines very quickly. We had huge success with the Ebola virus.”

Globally, roughly 20 coronavirus vaccine candidates are being developed by research institutes and drug-makers, including America’s Johnson & Johnson and France’s Sanofi SA, according to Reuters.

Two pharmaceutical companies in the U.S. are getting close to human testing.

Biotechnology company Moderna Inc. has announced plans to start a trial of a vaccine candidate on 45 people in Seattle this month. Testing on animals will proceed simultaneously with human trials, the NIH told Reuters.

Inovio Pharmaceuticals Inc., an immunotherapy company, is working with a company in China to develop a vaccine and expects to start human clinical trials in 30 U.S. volunteers in April.

Anthony Fauci, director of the National Institute of Allergy and Infectious Diseases, told the U.S. House Oversight and Reform Committee on Thursday that human trials for a vaccine would be possible “within a few weeks.”

“I want to make sure people understand, and I’ve said that over and over again, that does not mean we have a vaccine that we can use,” he said. “We mean it’s record time to get it tested. It’s going to take a year to a year and a half to really know if it works," Fauci said.

SPEAKERS BIOGRAPHIES

Gary Kobinger PhD, Pr. Dr., Director of the Research Centre on Infectious Diseases, Faculty of Medicine at Université Laval, Adjunct Professor, Department of Pathology and Laboratory Medicine, University of Pennsylvannia, Adjunct Professor, Department of Medical Microbiology, Faculty of Medicine, University of Manitoba, Canada.

Gary Kobinger is a professor in the Department of Microbiology and Infectious Diseases and the Director of the Research Centre on Infectious Diseases, Faculty of Medicine at Université Laval. **He is also an adjunct professor in the Department of Pathology and Laboratory Medicine at the University of Pennsylvania,** and an associate professor in the Department of Medical Microbiology at the University of Manitoba. His work focuses on developing and testing new vaccine platforms and immune treatments against emerging and re-emerging viruses of high consequences to public health.

Gary was granted several awards including the Faculty Teaching Award from the University of Manitoba, the 2014 the Gully award, the 2015 scientists of the year award from Radio Canada (CBC) and the Order of Manitoba in 2016.

Between 2013-2016, 60 minutes, National Geographic, BBC Horizon, NOVA, France 2, PBS and others featured the leading work on successful treatment of Ebola infection that was developed by Gary and his team. In July 2016, Gary Kobinger initiated a new chapter of his career as the Director of the Centre de Recherche en Infectiologie de l'Université Laval, Quebec, Canada.

[Note - The University of Pennsylvania is a private Ivy League research university in Philadelphia, Pennsylvania.]

Neal Koblitz (born 1948)

Wikipedia Neal Koblitz

See captured Wikipedia: [HK000F][GDrive]

Neal I. Koblitz (born December 24, 1948) is a Professor of Mathematics at the University of Washington. He is also an adjunct professor with the Centre for Applied Cryptographic Research at the University of Waterloo. He is the creator of hyperelliptic curve cryptography and the independent co-creator of elliptic curve cryptography.

Biography

Koblitz received his undergraduate degree from Harvard University in 1969. While at Harvard, he was a Putnam Fellow in 1968. He received his Ph.D. from Princeton University in 1974 under the direction of Nick Katz. From 1975 to 1979 he was an instructor at Harvard University.[2] In 1979 he began working at the University of Washington.

Koblitz's 1981 article "Mathematics as Propaganda" criticized the misuse of mathematics in the social sciences and helped motivate Serge Lang's successful challenge to the nomination of political scientist Samuel P. Huntington to the National Academy of Sciences.[4] In *The Mathematical Intelligencer*, Koblitz, Steven Weintraub, and Saunders Mac Lane later criticized the arguments of Herbert A. Simon, who had attempted to defend Huntington's work.

With his wife Ann Hibner Koblitz, he in 1985 founded the Kovalevskaia Prize, to honour women scientists in developing countries. It was financed from the royalties of Ann Hibner Koblitz's 1983 biography of Sofia Kovalevskaia. Although the awardees have ranged over many fields of science, one of the 2011 winners was a Vietnamese mathematician, Lê Thị Thanh Nhàn. Koblitz is an atheist.

2019 (July 13) Interview : Dr. Neal Koblitz: Independent Co-creator of Elliptic Curve Cryptography

Source article : [HW000I][GDrive]

Neal Koblitz and Victor Miller independently co-discovered elliptic-curve cryptography. In this interview with Dr. Koblitz, we learn about his life and passion for mathematics.

You might love math. You might love math enough that you've earned a degree for your studies. But do you love math enough to learn a Slavic language, travel behind the Iron Curtain during the height of the Cold War, and visit the only other Mathematics Center outside the US? Because that's how much Dr. Neal Koblitz loves math.

Dr. Neal Koblitz and Dr. Victor Miller independently co-discovered elliptic-curve cryptography (ECC), part of the mathematics that allows encrypted communication on the internet today. To learn what led these mathematicians to this breakthrough—and understand why these geniuses never patented their ideas—AAC's Mark Hughes spoke to Dr. Neal Koblitz.

If you're interested in the history of cryptography (especially during the Cold War) and want to hear what we can learn about modern cryptography, you may want to pull up a seat.

AAC: Tell us a little about your background and education.

NK: I have been interested in pure mathematics since I was a young child. When I went to college, I took courses in pure mathematics and a few courses in physics, but no engineering or other courses in practical application. My undergraduate work was at Harvard, and the department courses were very theoretical in nature. I never applied the math I was learning to real-life situations. I even learned calculus in a very abstract way.

I didn't actually learn about the applications of calculus until several years later when I started teaching it to students who were going into engineering, and the calculus I learned was completely inappropriate to those students. I had to teach the course in a very different way from the way I learned it.

In graduate school, I also studied an abstract area of mathematics: algebraic geometry in relation to number theory. That [area of mathematics] didn't give me any practical background—but, by happenstance, the subject of elliptic curves was central to my PhD thesis.

The same was true for the other fellow who came up with the ideas at the same time that I did. Victor Miller received his Ph.D. at Harvard at approximately

the same time I received my Ph.D. at Princeton in a similar area of mathematics; [we both were] doing a lot of work on elliptic curves.

But my background, and my early work into the 1980s, was in very theoretical mathematics. I had no grounding in applications.

AAC: When did your mathematics background shift from the theoretical realm to security applications?

NK: What changed my feeling about number theory was the invention of RSA cryptography (Rivest-Shamir-Adleman) in about 1977. That was the first important application of number theory to computer security. This really captured the imagination of a lot of people.

Many people who had previously thought of number theory as a purely theoretical area now saw that there might be some interesting work to be done in applications. Yet even in 1985, when I was thinking about using elliptic curves in cryptography, I had no idea that elliptic curve cryptography would ever be of great practical importance. (Author's note: Neither Dr. Koblitz nor Dr. Miller obtained patents for their work.)

AAC: I understand that you also spent some time in Russia. What compelled you to do that?

NK: When I was very young, during the Cold War between the United States and the Soviet Union, both countries were going all out to develop their scientific and technical capacity in a very competitive way. There was the race to the moon and other things like that.

The Soviet Union had at this point, in the 1960s, an extremely high level of theoretical mathematics. They were the only mathematical superpower besides the US. I realized at a young age that it would be really nice to be able to go over there and work with Soviet mathematicians, to learn how they do things. For this, I studied Russian intensively. In fact, as an undergraduate, I double-majored in Mathematics and Slavic Languages and Literature, which included Russian.

I was very serious about my studies and I started applying to study-abroad programs. In those days, it was much less common than now. I first went on a six-week summer language study program. My first trip to the Soviet Union was in 1967. After that, I went again as an independent tourist. Then, after I was married, my wife became very interested in Russian history, so we went again once I completed my PhD. We went several times in the 1970s and 1980s.

[By the 1970s,] at the advanced levels, there were some exchange programs. The National Academy of Sciences and the Soviet Union had an exchange program. So there were reasonable ways to get over there to spend a fair amount of time collaborating with Soviet specialists in theoretical mathematics. In 1985, I took my last long trip to the Soviet Union. That trip coincided with the starting of my work in cryptography.

The idea of elliptic-curve cryptography came in 1984. I, along with several other people received a pre-print, a rather preliminary-version, of an algorithm that Hendrik Lenstra developed to factor large integer numbers. If this algorithm was sufficiently fast, it could be a threat to RSA cryptography.

It turned out that this algorithm was not that much more efficient than other algorithms that existed at the time. [The algorithm] did not have a major impact on RSA, although it did have other uses in cryptography.

What fascinated us at the time is that Lenstra's algorithm used elliptic curves in a very fundamental way to attack a problem that, at first glance, didn't appear to involve elliptic curves—factoring integers. The fact that he was able to, in a clever way, use the geometry and number theory of elliptic curves to factor integers, was really intriguing. This was the first practical application of that sort of number theory, and I had that fresh in my mind when I went to the Soviet Union in 1984.

While I was in the Soviet Union, I thought that elliptic curves might be a really good basis for constructing a cryptosystem. I wrote about this idea to a mathematician I knew named Andrew Odlyzko, who worked at Bell Labs. Of the mathematicians I knew at the time, he was the person who most bridged the gap between pure and applied mathematics. He was knowledgeable about cryptography and had major work in pure number theory, so I mailed him this idea.

There was no email then, so replies were slow to come in through the mail. When I received his reply he said it was a good idea, and that Victor Miller of IBM had suggested the same thing that I was suggesting. He encouraged me, and I suspect Victor Miller, to pursue it. He saw no fallacies in basing a cryptosystem on what Victor and I suggested.

AAC: You obviously found your time in the USSR valuable. What were they doing differently and what were you gaining from the experience that you couldn't find in the United States?

NK: This [last trip to the Soviet Union] was planned before I really started working in cryptography. That trip was my last long visit—six months in 1985. No one in the Soviet Union worked openly on cryptography.

Even in the US in early years, there was a lot of controversy about whether people other than employees of the government working for the NSA should be permitted to study cryptography or permitted to publish their work on it. There were attempts by the NSA to restrict and create a [government] monopoly on cryptography research.

Ultimately, the people in the government that wanted to [restrict cryptography research] lost the battle. But in the Soviet Union, the governments did not want anybody outside government to be working on cryptography, and nobody did so. There was no way I could collaborate with anyone in the Soviet Union on cryptography, and in any case, I was just a beginner at that time.

During the time I was visiting the Soviet Union, I was still working in pure number theory and they had some of the top people in the world. One of them, named Yuri Manin, was one of the top Soviet specialists in number theory. I worked under his guidance for a couple of my trips—but when I came in 1985, he'd changed his interests to mathematical physics which I was not working or interested in.

In addition, since nobody was working in cryptography, my visit in 1985 was not as productive as my previous visits.

Ultimately, the people in the government that wanted to [restrict cryptography research] lost the battle. But in the Soviet Union, the governments did not want anybody outside government to be working on cryptography, and nobody did so. There was no way I could collaborate with anyone in the Soviet Union on cryptography, and in any case, I was just a beginner at that time.

During the time I was visiting the Soviet Union, I was still working in pure number theory and they had some of the top people in the world. One of them, named Yuri Manin, was one of the top Soviet specialists in number theory. I worked under his guidance for a couple of my trips—but when I came in 1985, he'd changed his interests to mathematical physics which I was not working or interested in.

In addition, since nobody was working in cryptography, my visit in 1985 was not as productive as my previous visits.

I'd gone over for a full year in 1974-1975, and six months in 1978. There, working in Moscow, it was really a unique experience because it was the biggest

concentration of mathematicians anywhere in the world at the time.

It's not that there weren't a very large number of mathematicians in the US, but they weren't all in one place. The US is much more decentralized. In the Soviet Union, as in many other countries, a disproportionate amount of scientific work is in the capital or one central location. This brings the top minds in a field all to one place. [In Moscow,] you could have a highly specialized seminar where 30, 40, 50 people attend whereas in the US that wouldn't be likely except at a large conference, but certainly not on a routine basis. So that was a thrilling experience... and stimulating.

Another thing I found both stimulating and intimidating was that the Soviet students were a lot more advanced than we were at the undergraduate level. In America, even the most serious math students normally wouldn't publish papers [as undergraduates] but in the Soviet Union the best students started publishing papers when they were juniors and seniors in college—and they were quite good papers.

When I went over there from Harvard and met Soviet students my age, they would ask me what the professors at Harvard were working on right now and I had no idea. I knew what courses they were teaching us students, but I had no idea what their research was. I felt pretty backward compared to [Russian] students and I thought I was pretty advanced for an American student.

AAC: You chose to get involved with the technical community in Vietnam. What can you tell us about that time period?

NK: My wife and I were very active in the student movement against the war in Vietnam. And a certain number of people who had been involved in the anti-war movement wanted to see if we could do something to support Vietnam because it was so badly destroyed during the war. Not just human suffering, but also economic and environmental destruction.

It was very hard for the people of Vietnam to recover from the war. There were some people in the West who were trying to in some ways help out. Vietnam was isolated because the US refused to have any diplomatic relations with Vietnam for about 20 years. So there were a lot of limitations and scientists in the West were in a position to help out.

A group of us called the US Committee for Scientific Cooperation with Vietnam encouraged their scientists with channels of communication to bring publications, send books, give guest lectures, and other things to help overcome the isolation the scientists were suffering from.

In the 1980s, my wife and I found out that in Vietnam, like other countries, there were big problems with the underrepresentation of women in the science and technical areas. On one visit, we talked to the head of the Hanoi Polytechnic Institute and we asked what proportion of the students are women—and they said 8%. We said, "That's terrible—we're going to help."

After consulting with some top Vietnamese scientists and mathematicians, we decided to start an annual prize for women in science, technology, and medicine that was coordinated with the Women's Union—the Kovalevskaia Fund. This has been going on for the 34 years since 1985 and has been very successful in terms of its visibility in Vietnam. It's very well publicized for a long period of time.

Until her retirement, the head of the committee that selects the winners in Vietnam was probably the most famous living woman in Vietnam. For that reason, the prize has gotten a lot of publicity and we've been encouraged to think that a lot of young women are very much aware of it and that encourages them to go into scientific and technical areas.

AAC: What should everyone know about the Kovalevskaia Prizes?

NK: The award is named after the 19th-century female Russian Mathematician Sofia Kovalevskaya. She was the first woman mathematician from any country to be a full member of the elite academic community of mathematicians. She was a full professor in Sweden and became a very active member of the European mathematical establishment.

While she was certainly not the first important woman mathematician, she was the first one to get full recognition for her accomplishments. That was surprising to a lot of people because Russian in the 19th century was considered somewhat backward country, so this woman was really a pioneer. There was no one in the west with her accomplishments in mathematics and other fields. There were so many restrictions against women in the universities of the world, hers was a unique achievement.

Quite a few of the Vietnamese best scientists studied in the Soviet Union, and there was a lot of exchange between the two countries. My wife wrote her doctoral thesis and a book on Kovalevskaya and we wanted to commemorate her through this prize.

AAC: Tell me about your views on the current field of cryptography. What does modern security need?

NK: The main weaknesses have to do with poor implementation, not using the cryptography that's available, or using it improperly.

Sometimes shortcuts are taken by companies that provide keys that lead to big problems later on: inadequate security, inadequate key length, outmoded systems, and so on. There is a lot of reluctance to change from the software you know.

A long time ago, it was recommended that either people change from RSA to ECC or to greatly increase their RSA key size. But I don't think everybody has done that yet even to this day. I think there are still a lot of weak keys lying around that could be attacked.

Now, in practice, weak cryptography does not necessarily cause huge amounts of problems because nobody with a lot of resources is really motivated to break into it. Sometimes people can get away with using fairly weak cryptography that if, say, the NSA or the Russian mafia or somebody were really determined they could break it. But if they are not interested, they have no reason to break into your system.

So if you're using fairly weak cryptography to protect your credit card numbers, you might find that the type of people who steal credit-card numbers don't have the resources to break it, and the people who do have the resources to break it simply don't care. So you can get away with weak cryptography if you're not a tempting target.

There are all sorts of problems in social engineering that frequently use phishing attacks and things like that. People use weak passwords and use the same passwords in different systems. People can use a password from a weak system to break into a strong system.

In all the cases I know of, breaches are not the result of weaknesses in the fundamental cryptography that's available, it's really because of the failure to use cryptography, failure to set it up correctly, taking shortcuts, social engineering, organizational problems, or system level problems.

But the basic types of cryptography that have been used—and that includes RSA, which is now 42 years old—is really sound.

You have to increase to quite large keys in RSA because of all the progress in factoring, but it's still basically a good system—so is ECC. The basic security of

RSA and ECC have really stood the test of time.

There have been many successful breaks in both, for example, the Sony disaster where the DRM was completely broken in 2011 because they used the same random number. They were supposed to choose a different random number for every signature and they just hardwired a single random number for everything and it made it absolutely trivial to break the system and find the secret keys.

The hack wasn't because ECC is a bad system, it was because there are certain things that are very important in implementing ECC and they ignored one of the crucial components. There are a lot of dangers that come from poor implementation and inadequate implementation where you are carefully locking the front door and meanwhile the back door is wide open.

Summary

The elliptic curve cryptography that Dr. Koblitz and Dr. Miller invented so many decades ago remains one of the best ways to protect data exchanges for embedded microcontrollers. "Hacks" do not break the mathematics of elliptic curve cryptography, at least not yet. But the hackers don't need to defeat the mathematics when it is so much simpler to look for poor implementations by a security engineer.

But it turns out that co-inventing ECC is not the only extraordinary thing about Dr. Neal Koblitz.

When some people see a problem, they say, "Someone should do something about that." When some people organize an award, they name it after themselves as a reminder to others of their magnanimity. When most people are interested in a subject, they go so far as visiting the local library to check out a book.

I hope you realize from this interview that Dr. Koblitz is not like most people.

Koblitz is a man of principle and action. He learned a new language so he could travel to a faraway place during the heights of the Cold War. He saw destruction after war and disrupted his life to help rebuild Vietnam. He created an award attributed to the greatness of another mathematician to raise the hopes and dreams of schoolchildren so that they, too, might one day be great.

- Thesis : Diagnosis and epidemiology of torovirus infections in cattle (1990)

Maria Petronella Gerarda Koopmans[1] (born 21 September 1956) is a Dutch virologist who is Head of the Erasmus MC Department of Viroscience. Her research considers emerging infectious diseases, noroviruses and veterinary medicine. In 2018 she was awarded the Netherlands Organisation for Scientific Research (NWO) Stevin Prize. She serves on the scientific advisory group of the World Health Organization.

Early life and education

Koopmans studied veterinary medicine at Utrecht University.[2] She graduated from her Master's degree 1976, and remained there for her doctoral research. She earned two graduate degrees in veterinary medicine, and was officially registered as a veterinary microbiologist in 1977. She became increasingly interested in virology, and moved to the United States to specialise in viruses that can be transmitted between animals and humans.[3] From 1991 to 1994 Koopmans completed a fellowship at the Centers for Disease Control and Prevention, where she studied enteric viruses.[2] She joined the Virology Division, where she focussed on torovirus in cattle.

Research and career

Koopmans joined the National Institute for Public Health and the Environment (RIVM), where she was appointed Chief of Virology. She was involved with restructuring the department, and translating their research out of the laboratory and into practical applications for the control of infectious diseases. In 2006 she was appointed as Professor of Public Health at the Erasmus MC hospital in Rotterdam, which allowed her to strengthen the evidence-base of infectious disease research. Her laboratory makes use of basic scientific studies and epidemiology to understand the pathogenesis of infectious diseases, to establish their transmission routes and to translate this research base into diagnostic tools.

In 2003, when Influenza A virus subtype H7N7 spread around the Netherlands, Koopmans experienced her first infectious diseases outbreak. She was involved with the development of a coordinated public response, working with veterinarians and physicians to quickly develop public health policy. Her experiences in leading the response to the avian influenza outbreak prepared her for subsequent epidemics, including Middle East respiratory syndrome (MERS) and Zika virus. She was on the team that found, in 2013, that dromedary camels were an intermediate host for the virus that causes MERS.[4] She has since worked with Elmoubasher Farag to test camels for antibodies against MERS.[5]

During the Ebola outbreak in West Africa, Koopmans was responsible for the deployment of mobile laboratories in Sierra Leone and Liberia. Her Erasmus MC team trained volunteers to run testing and treatment programmes.[6] Koopmans is a member of the scientific advisory group (SAG) of the World Health Organization's R&D Blueprint project.[7] The project looks to understand what has gone wrong with epidemic and pandemic responses, and looks to build global disease preparedness.[7] As part of this effort, Koopmans analysed the public health response to the Zika virus. She identified three significant bottlenecks to an efficient response; including delays in regulatory approvals, challenges in the logistics of laboratory support and the absence of a structured timeline for funding.[8] Koopmans also leads the World Health Organization centre for Emerging Viral Diseases.[9] She is the scientific coordinator of COMPARE, a Horizon 2020 project that looks to develop next generation sequencing techniques for outbreak identification and mapping.[10] COMPARE look to contain and mitigate foodborne illnesses.[10]

In 2018 Koopmans was honoured by the Netherlands Organisation for Scientific Research (NWO) for her work on the transfer of viruses from animals to humans.[11] In 2019 she was awarded a $9 million NWO grant to establish a consortium, the Versatile Emerging infectious disease Observatory (VEO), that will study how changes in environment and travel will impact the risk of infectious diseases.[12][13] The diseases considered by VEO include vector-borne and zoonotic diseases, as well as hidden pathogens.[14] Koopmans wrote an article for Nature in which she called for a transformation in epidemic preparedness and response.[15] In the article, she quoted the World Health Organization's leader on health emergencies, “We are entering a very new phase of high-impact epidemics… This is a new normal,”[16] In 2019 Koopmans was elected member of the Royal Netherlands Academy of Arts and Sciences.[17]

From the start of 2020, Koopmans worked to understand SARS-CoV-2 and the spread of coronavirus disease.[3][18][19] In the Netherlands, Koopmans made an effort to test healthcare workers, and identified that there were large numbers of asymptomatic carriers amongst the dutch population.[20] With her team at the Erasmus MC, Koopmans looked to understand the efficacy of antibody tests.[21][22] Alongside leading the scientific response, Koopmans was also involved with scientific communication about the virus, making use of social media and media interviews to share up-to-date research with the public.[23][24] Koopmans said that as humans occupied more of planet earth, the number of dangerous diseases transmitted from animals to humans would increase.[25] She was appointed to the coronavirus disease advisory panel of the European Commission.[25] The panel served to develop public health recommendations to the member states during the pandemic.[25]

On 02 December 2020, Koopmans was appointed to the 13 member team of the World Health Organization's investigation into the origins of COVID-19.[26]

Awards and honours

- 2004 Dutch Association for Infectious Diseases WRO Goslings Prize [27]
- 2017 Technical University of Denmark Honorary Doctorate Honorary Doctor [28]
- 2018 Netherlands Organisation for Scientific Research Stevin Prize[11]

2020 (Jan 4) - StatNews : "Experts search for answers in limited information about mystery pneumonia outbreak in China"

By Helen Branswell Jan. 4, 2020 / Source : [HM001F][GDrive]

The mysterious and growing cluster of unexplained pneumonia cases in the Chinese city of Wuhan has infectious disease experts parsing limited public statements from Chinese authorities for clues to what is happening.

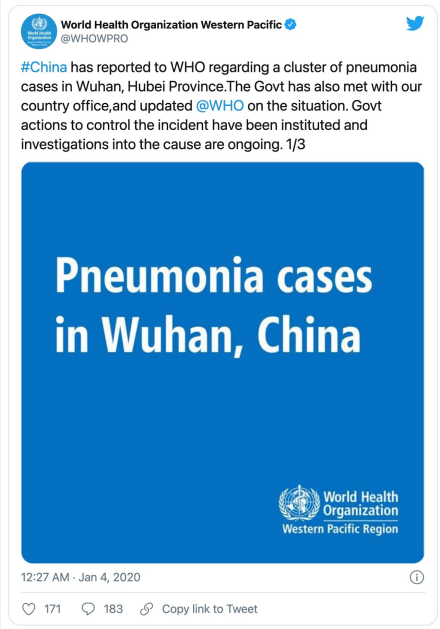
With machine-translated reports that the outbreak might be caused by a new virus, and perhaps even a new coronavirus — the family of viruses that produced both SARS and MERS — watchers are hoping that Chinese authorities will provide additional information soon.

"I think we need to give them a couple of days but I want to hear something from a credible source on the investigations that are ongoing," said Marion Koopmans, director of the department of virology at Erasmus Medical Center in Rotterdam, the Netherlands.

As of Friday, health authorities in Wuhan reported 44 cases, a big jump from the 27 reported on Tuesday. Eleven of the 44 were seriously ill, the Wuhan Municipal Health Commission said, though **there were no reported deaths to date**. The health of 121 close contacts of the cases was being monitored. **The infections are linked to a large seafood market where it is believed some exotic animals were also sold for consumption.**

The World Health Organization has said little about the outbreak beyond that it is in close contact with China authorities on the issue.

"We're closely monitoring the situation in Wuhan and are in active communication with our counterparts in China," WHO's regional office for the Western Pacific Region, which includes China, said on Twitter. "We've activated our incident management system across the three levels of WHO (country office, regional office, HQ) and can launch a broader response, if needed."



[HM001G][GDrive]

The agency noted that China "has extensive capacity to respond to public health events and is responding proactively and rapidly to the current incident in Wuhan — isolating patients, tracing close contacts, cleaning up the market, and searching for the cause and for additional cases."

Ralph Baric, a coronavirus expert at the University of North Carolina, agreed that China has deep expertise in virology. Baric has a collaborative grant with some researchers in Wuhan to study emerging coronaviruses, and has visited the facilities there.

"Wuhan is the epicenter for a lot of virology research in China. They have state of the art BSL3 and BSL4 facilities and world-class facilities to do anything that you would want to do on new emerging infectious diseases. So it's occurring in the right spot," he said.

BSL is shorthand for the bio-safety level designation of a laboratory; level 3 and level 4 are the labs in which the most dangerous pathogens are worked on.

Social media platforms — both in China and outside it — have been abuzz with discussion of the Wuhan outbreak, with some commentators arguing the lack of a clear answer by now is reminiscent of China's behavior during the 2002-2003 SARS outbreak.

But Baric disagreed, saying China's approach to infectious disease outbreaks has evolved considerably since SARS, an event for which it was harshly criticized globally.

"The situation in China between 2003 and 2020 is night and day," he said. "They have many of the best virologists in the world there that are working on this. And my gut feeling is we're going to see a showcase of what they've accomplished in 20 years."

Koopmans and Baric have a number of questions they'd like answered — "very soon," Koopmans said — to help assess the severity of the situation.

Knowing whether Chinese scientists have identified the cause of the illness is top of the list. Whether it is indeed a new virus — and what viral family it belongs to — is right up there too.

During the SARS outbreak, it took a full month from when the WHO tasked a global network of 11 laboratories to find the cause of the outbreak before confirmation was received that a new coronavirus was the culprit. The SARS coronavirus probably originated in bats, but civet cats — wild animals eaten as a delicacy in southern China — were the virus' route to people.

Technology has improved a lot since then, said Baric, who said multiplexing PCR — polymerase chain reaction testing — and RNA-Seq, which looks for evidence of the RNA of pathogens in clinical samples, could make finding the culprit a much quicker job this time round.

But even with the new technology, finding the cause of pneumonia can be tricky. With some infections, by the time a person is evidently ill, their immune system has cleared away most of the causative agent. The symptoms of illness are actually the effect the cascade of immune system weapons unleashed on tissues that had been infected.

"There's a window there of viral detection of the viral nucleic acid," Baric said.

"If most of these initial patients were caught late in infection, when the more severe disease symptoms came on, they may not have any acute cases and it may be very difficult. Very low levels of nucleic acid to chase to discover the disease."

Koopmans noted finding the cause may be complicated by the fact that pneumonia is common and can be caused by many pathogens. If authorities started looking for pneumonia cases after realizing there was a problem in Wuhan, some of the cases they found might have been unrelated to the actual event.

Both are keen to know if there is any spread of the illness between people, which would be worrying. Wuhan health authorities have said there was no human-to-human transmission. But unless they know what is causing the illness, how long the illness takes to develop, and have developed a test that can detect mild cases, it is not clear that can be ruled out at this point.

"I don't find the comments [about human transmission] that I see spread throughout the internet as credible — unless they know what it is," Baric said.

The fact that health officials in Wuhan closed and decontaminated the seafood market — there is video of this happening on social media — is suggestive that an animal virus had spilled over into people, he added.

The statement from the Wuhan health board said that influenza, avian influenza, and adenovirus infections — the latter can cause serious respiratory illness — have been ruled out.

Because of SARS, attention is focusing on coronaviruses, though both Koopmans and Baric noted a number of different virus families could cause respiratory outbreaks.

But coronaviruses have shown themselves to be adept at jumping from animal hosts to people, sometimes establishing themselves as human pathogens. There are four human coronaviruses that are common causes of cold-like illness. Those viruses were formerly animal viruses — experts can tell by comparing their genetic sequences to animal coronaviruses. When the four started infecting humans is not clear in most cases.

Some coronaviruses have jumped from animals to people on multiple occasions — the MERS virus in the Arabian Peninsula is an example — but haven't acquired the ability to spread easily from person to person.

Sometimes the damage can be significant.

In late November of 2002, people in the southern Chinese province of Guangdong started to become ill from unexplained pneumonias. The WHO began hearing rumors of the illness, but Chinese authorities played it down.

But in late February, travelers from a number of countries — Vietnam, Singapore, Canada among them — stayed on the same floor in a Hong Kong hotel as a doctor from China who had been looking after some of the pneumonia cases. He was ill, and he infected multiple other hotel guests, seeding the new infection across Southeast Asia and to Toronto.

Transmission of the new disease was stopped by the summer of 2003, but in its short history SARS — short for severe acute respiratory syndrome — infected more than 8,000 people and killed nearly 800.

Baric said he's hopeful Chinese scientists will have figured out what is going on in Wuhan and will report on it soon.

"If the number of cases keeps increasing, then it becomes more and more of a global public health threat," he said. "The chance of [infected] people slipping through the screening platforms for international travel or travel elsewhere in China become greater as long as they don't know what the pathogen is."

A Novel Coronavirus Emerging in China — Key Questions for Impact Assessment

Vincent J. Munster, Ph.D., Marion Koopmans, D.V.M., Neeltje van Doremalen, Ph.D., Debby van Riel, Ph.D., and Emmie de Wit, Ph.D.

A novel coronavirus, designated as 2019-nCoV, emerged in Wuhan, China, at the end of 2019. As of January 24, 2020, at least 830 cases had been diagnosed in nine countries: China, Thailand, Japan, South Korea, Singapore, Vietnam, Taiwan, Nepal, and the United States. Twenty-six fatalities occurred, mainly in patients who had serious underlying illness.[1] Although many details of the emergence of this virus — such as its origin and its ability to spread among humans — remain unknown, an increasing number of cases appear to have resulted from human-to-human transmission. Given the severe acute respiratory syndrome coronavirus (SARS-CoV) outbreak in 2002 and the Middle East respiratory syndrome coronavirus (MERS-CoV) outbreak in 2012,[2] 2019-nCoV is the third coronavirus to emerge in the human population in the past two decades — an emergence that has put global public health institutions on high alert.

China responded quickly by informing the World Health Organization (WHO) of the outbreak and sharing sequence information with the international community after discovery of the causative agent. The WHO responded rapidly by coordinating diagnostics development; issuing guidance on patient monitoring, specimen collection, and treatment; and providing up-to-date information on the outbreak.[3] Several countries in the region as well as the United States are screening travelers from Wuhan for fever, aiming to detect 2019-nCoV cases before the virus spreads further. Updates from China, Thailand, Korea, and Japan indicate that the disease associated with 2019-nCoV appears to be relatively mild as compared with SARS and MERS.

After initial reports of a SARS-like virus emerging in Wuhan, it appears that 2019-nCoV may be less pathogenic than MERS-CoV and SARS-CoV (see table). However, the virus's emergence raises an important question: What is the role of overall pathogenicity in our ability to contain emerging viruses, prevent large-scale spread, and prevent them from causing a pandemic or becoming endemic in the human population? Important questions regarding any emerging virus are, What is the shape of the disease pyramid? What proportion of infected people develop disease? And what proportion of those seek health care? These three questions inform the classic surveillance pyramid (see diagram).[4] Emerging coronaviruses raise an additional question: How widespread is the virus in its reservoir? Currently, epidemiologic data that would allow us to draw this pyramid are largely unavailable (see diagram).

[HP005C][GDrive]

Table 1. Pathogenicity and Transmissibility Characteristics of Recently Emerged Viruses in Relation to Outbreak Containment.

Virus	Case Fatality Rate (%)	Pandemic	Contained	Remarks
2019-nCoV	Unknown*	Unknown	No, efforts ongoing	
pH1N1	0.02–0.4	Yes	No, postpandemic circulation and establishment in human population	
H7N9	39	No	No, eradication efforts in poultry reservoir ongoing	
NL63	Unknown	Unknown	No, endemic in human population	
SARS-CoV	9.5	Yes	Yes, eradicated from intermediate animal reservoir	58% of cases result from nosocomial transmission
MERS-CoV	34.4	No	No, continuous circulation in animal reservoir and zoonotic spillover	70% of cases result from nosocomial transmission
Ebola virus (West Africa)	63	No	Yes	

* Number will most likely continue to change until all infected persons recover.

Clearly, efficient human-to-human transmission is a requirement for large-scale spread of this emerging virus. However, the severity of disease is an important indirect factor in a virus's ability to spread, as well as in our ability to identify those infected and to contain it — a relationship that holds true whether an outbreak results from a single spillover event (SARS-CoV) or from repeated crossing of the species barrier (MERS-CoV).

If infection does not cause serious disease, infected people probably will not end up in health care centers. Instead, they will go to work and travel, thereby potentially spreading the virus to their contacts, possibly even internationally. Whether subclinical or mild disease from 2019-nCoV is also associated with a reduced risk of virus spread remains to be determined.

Much of our thinking regarding the relationship between transmissibility and pathogenicity of respiratory viruses has been influenced by our understanding of influenza A virus: the change in receptor specificity necessary for efficient human-to-human transmission of avian influenza viruses leads to a tropism shift from the lower to the upper respiratory tract, resulting in a lower disease burden. Two primary — and recent — examples are the pandemic H1N1 virus and the avian influenza H7N9 virus. Whereas the pandemic H1N1 virus — binding to receptors in the upper respiratory tract — caused relatively mild disease and became endemic in the population, the H7N9 virus — binding to receptors in the lower respiratory tract — has a case-fatality rate of approximately 40% and has so far resulted in only a few small clusters of human-to-human transmission.

It is tempting to assume that this association would apply to other viruses as well, but such a similarity is not a given: two coronaviruses that use the same receptor (ACE2) — NL63 and SARS-CoV — cause disease of different severity. Whereas NL63 usually causes mild upper respiratory tract disease and is endemic in the human population, SARS-CoV induced severe lower respiratory tract disease with a case-fatality rate of about 11% (see table). SARS-CoV was eventually contained by means of syndromic surveillance, isolation of patients, and quarantine of their contacts. Thus, disease severity is not necessarily linked to transmission efficiency.

Even if a virus causes subclinical or mild disease in general, some people may be more susceptible and end up seeking care. The majority of SARS-CoV and MERS-CoV cases were associated with nosocomial transmission in hospitals,[5] resulting at least in part from the use of aerosol-generating procedures in patients with respiratory disease. In particular, nosocomial super-spreader events appear to have driven large outbreaks within and between health care settings. For example, travel from Hong Kong to Toronto by one person with SARS-CoV resulted in 128 SARS cases in a local

[HP005D][GDrive]

A novel coronavirus, desygnated as 2019-nCoV, emerged in Wuhan, China, at the end of 2019. As of January 24, 2020, at least 830 cases had been diagnosed in nine countries: China, Thailand, Japan, South Korea, Singapore, Vietnam, Taiwan, Nepal, and the United States. Twentysix fatalities occurred, mainly in patients who had serious underlying illness.1 Although many details of the emergence of this virus — such as its origin and its ability to spread among humans — remain unknown, an increasing number of cases appear to have resulted from human-to-human transmission. Given the severe acute respiratory syndrome coronavirus (SARS-CoV) outbreak in 2002 and the Middle East respiratory syndrome coronavirus (MERS-CoV) outbreak in 2012,2 2019-nCoV is the third coronavirus to emerge in the human population in the past two decades — an emergence that has put global public health institutions on high alert.

China responded quickly by informing the World Health Organization (WHO) of the outbreak and sharing sequence information with the international community after discovery of the causative agent. The WHO responded rapidly by coordinating diagnostics development; issuing guidance on patient monitoring, specimen collection, and treatment; and providing up-to-date information on the outbreak.3 Several countries in the region as well as the United States are screening travelers from Wuhan for fever, aiming to detect 2019-nCoV cases before the virus spreads further. Updates from China, Thailand, Korea, and Japan indicate that the disease associated with 2019-nCoV appears to be relatively mild as compared with SARS and MERS.

After initial reports of a SARS-like virus emerging in Wuhan, it appears that 2019-nCoV may be less pathogenic than MERS-CoV and SARS-CoV (see table). However, the virus's emergence raises an important question: What is the role of overall pathogenicity in our ability to contain emerging viruses, prevent large-scale spread, and prevent them from causing a pandemic or becoming endemic in the human population? Important questions regarding any emerging virus are, What is the shape of the disease pyramid? What proportion of infected people develop disease? And what proportion of those seek health care? These three questions inform the classic surveillance pyramid (see diagram).4 Emerging coronaviruses es raise an additional question: How widespread is the virus in its reservoir? Currently, epidemiologic data that would allow us to draw this pyramid are largely unavailable (see diagram).

Clearly, efficient human-to-human transmission is a requirement for large-scale spread of this emerging virus. However, the severity of disease is an important indirect factor in a virus's ability to spread, as well as in our ability to identify those infected and to contain it — a relationship that holds true whether an outbreak results from a single spillover event (SARS-CoV) or from repeated crossing of the species barrier (MERS-CoV).

If infection does not cause serious disease, infected people probably will not end up in health care centers. Instead, they will go to work and travel, thereby potentially spreading the virus to their contacts, possibly even internationally. Whether subclinical or mild disease from 2019-nCoV is also associated with a reduced risk of virus spread remains to be determined.

Much of our thinking regarding the relationship between transmissibility and pathogenicity of respiratory viruses has been influenced by our understanding of influenza A virus: the change in receptor specificity necessary for efficient human-to-human transmission of avian influenza viruses leads to a tropism shift from the lower to the upper respiratory tract, resulting in a lower disease burden. Two primary — and recent — examples are the pandemic H1N1 virus and the avian influenza H7N9 virus. Whereas the pandemic H1N1 virus — binding to receptors in the upper respiratory tract — caused relatively mild disease and became endemic in the population, the H7N9 virus — binding to receptors in the lower respiratory tract — has a case-fatality rate of approximately 40% and has so far resulted in only a few small clusters of human-to-human transmission.

It is tempting to assume that this association would apply to other viruses as well, but such a similarity is not a given: two coronaviruses that use the same receptor (ACE2) — NL63 and SARS-CoV — cause disease of different severity. Whereas NL63 usually causes mild upper respiratory tract disease and is endemic in the human population, SARS-CoV induced severe lower respiratory tract disease with a case-fatality rate of about 11% (see table). SARS-CoV was eventually contained by means of syndromic surveillance, isolation of patients, and quarantine of their contacts. Thus, disease severity is not necessarily linked to transmission efficiency.

Even if a virus causes subclinical or mild disease in general, some people may be more susceptible and end up seeking care. The majority of SARS-CoV and MERSCoV cases were associated with nosocomial transmission in hospitals, 5 resulting at least in part from the use of aerosol-generating procedures in patients with respiratory disease. In particular, nosocomial super-spreader events appear to have driven large outbreaks within and between health care settings. For example, travel from Hong Kong to Toronto by one person with SARS-CoV resulted in 128 SARS cases in a local hospital. Similarly, the introduction of a single patient with MERSCoV from Saudi Arabia into the South Korean health care system resulted in 186 MERS cases.

The substantial involvement of nosocomial transmission in both SARS-CoV and MERS-CoV outbreaks suggests that such transmission is a serious risk with other newly emerging respiratory coronaviruses. In addition to the vulnerability of health care settings to outbreaks of emerging coronaviruses, hospital populations are at significantly increased risk for complications from infection. Age and coexisting conditions (such as diabetes or heart disease) are independent predictors of adverse outcome in SARS-CoV and MERS-CoV. Thus, emergingviruses that may go undetected because of a lack of severe disease in healthy people can pose significant risk to vulnerable populations with underlying medical conditions.

A lack of severe disease manifestations affects our ability to contain the spread of the virus. Identification of chains of transmission and subsequent contact tracing are much more complicated if many infected people remain asymptomatic or mildly symptomatic (assuming that these people are able to transmit the virus). More pathogenic viruses that transmit well between humans can generally be contained effectively through syndromic (fever) surveillance and contact tracing, as exemplified by SARS-CoV and, more recently, Ebola virus. Although containment of the ongoing Ebola virus outbreak in the Democratic Republic of Congo is complicated by violent conflict, all previous outbreaks were contained through identification of cases and tracing of contacts, despite the virus's efficient person-to-person transmission.

We currently do not know where 2019-nCoV falls on the scale of human-to-human transmissibility. But it is safe to assume that if this virus transmits efficiently, its seemingly lower pathogenicity as compared with SARS, possibly combined with super-spreader events in specific cases, could allow large-scale spread. In this manner, a virus that poses a low health threat on the individual level can pose a high risk on the population level, with the potential to cause disruptions of global public health systems and economic losses. This possibility warrants the current aggressive response aimed at tracing and diagnosing every infected patient and thereby breaking the transmission chain of 2019-nCoV.

Epidemiologic information on the pathogenicity and transmissibility of this virus obtained by means of molecular detection and serosurveillance is needed to fill in the details in the surveillance pyramid and guide the response to this outbreak. Moreover, the propensity of novel coronaviruses to spread in health care centers indicates a need for peripheral health care facilities to be on standby to identify potential cases as well. In addition, increased preparedness is needed at animal markets and other animal facilities, while the possible source of this emerging virus is being investigated. If we are proactive in these ways, perhaps we will never have to discover the true epidemic or pandemic potential of 2019-nCoV.

Dr. Hilary Koprowski (born 1916)

Dr. Hilary Koprowski developed an effective polio vaccine before Jonas Salk and Albert Sabin. It was used overseas with good results, but it was never approved for use in the United States. Credit... Yale Joel/Time Life Pictures, via Getty Images

Hilary Koprowski (5 December 1916 – 11 April 2013) was a Polishvirologist and immunologist active in the United States who demonstrated the world's first effective live polio vaccine. He authored or co-authored over 875 scientific papers and co-edited several scientific journals.

Koprowski received many academic honors and national decorations, including the Belgian Order of the Lion, the French Order of Merit and Legion of Honour, Finland's Order of the Lion, and Order of Merit of the Republic of Poland.

Koprowski was the target of accusations in the press related to the "oral polio vaccine AIDS hypothesis", which posited that the AIDS pandemic originated from live polio vaccines such as Koprowski's. This allegation has long been contested by claims that the HIV-1 virus was introduced to humans before his polio-vaccine trials were conducted in Africa.[1] The case was settled out of court with a formal apology from Rolling Stonemagazine.[2]

Life

Hilary Koprowski was born in Warsaw to an educated, assimilated Jewish family.[3][4] His parents met in 1906 when Paweł Koprowski (1882–1957) was serving in the Imperial Russian Army, and moved to Warsaw soon after their marriage in 1912.[5] His mother Sonia (née Berland; 1883–1967), was a dentist from Berdichev.[6][7] Hilary Koprowski attended Warsaw's Mikołaj Rej Secondary School, and from age twelve he took piano lessons at the Warsaw Conservatory. He received a medical degree from Warsaw University in 1939. He also received music degrees from the Warsaw Conservatory and, in 1940, from the Santa Cecilia Conservatory in Rome. He adopted scientific research as his life's work, but never gave up music and composed several musical works. In July 1938, while in medical school, Koprowski married Irena Grasberg.[8]

In 1939, after Germany's invasion of Poland, Koprowski and his wife, likewise a physician, fled the country, using Koprowski family business connections in Manchester, England. Hilary went to Rome, where he spent a year studying piano at the Santa Cecilia Conservatory; while Irena went to France, where she gave birth to their first child, Claude Koprowski, and worked as an attending physician at a psychiatric hospital.[9]

As the invasion of France loomed in 1940, Irena and the infant escaped from France via Spain and Portugal —where the Koprowski family reunited — to Brazil, where Koprowski worked in Rio de Janeiro for the Rockefeller Foundation. His field of research for several years was finding a live-virus vaccine against yellow fever. After World War II the Koprowskis settled in Pearl River, New York, where Hilary was hired as a researcher for Lederle Laboratories, the pharmaceutical division of American Cyanamid. Here he began his polio experiments, which ultimately led to the creation of the first oral polio vaccine. Koprowski served as director of the Wistar Institute, 1957–91, during which period Wistar achieved international recognition for its vaccine research and became a National Cancer Institute Cancer Center.[citation needed]

Koprowski died on April 11, 2013, aged 96,[10][11] in Wynnewood, near Philadelphia, Pennsylvania, of pneumonia.[12] He and his wife are buried at West Laurel Hill Cemetery, Southlawn Section, Lot 782, Bala Cynwyd, Pennsylvania.

Hilary Koprowski and his late wife are survived by two sons, Claude (born in Paris, 1940) and Christopher (born 1951). Claude Koprowski is a retired physician. Christopher Koprowski is a physician certified in two specialties, neurology and radio-oncology; he is the former chair of the department of radiation oncology at Christiana Hospital in Delaware.[13]

Polio vaccine

While at Lederle Laboratories,[10] Koprowski created the world's first polio vaccine, based on an orally administered attenuated polio virus. In researching a potential polio vaccine, he had focused on live viruses that were attenuated (rendered non-virulent) rather than on killed viruses (the latter became the basis for the injected vaccine subsequently developed by Jonas Salk).

Koprowski viewed the live vaccine as more powerful, since it entered the intestinal tract directly and could provide lifelong immunity, whereas the Salk vaccine required booster shots. Also, administering a vaccine by mouth is easy, whereas an injection requires medical facilities and is more expensive.[citation needed]

Koprowski developed his polio vaccine by attenuating the virus in brain cells of a cotton rat, Sigmodon hispidus, a New World species that is susceptible to polio.[10] He administered the vaccine to himself in January 1948 and, on 27 February 1950, to 20 children at Letchworth Village, a home for disabled persons in Rockland County, New York. Seventeen of the 20 children developed antibodies to polio virus — the other three apparently already had antibodies — and none of the children developed complications. Within 10 years, the vaccine was being used on four continents.

[**Dr. Albert Bruce Sabin (born 1906)**]'s early work with attenuated-live-virus polio vaccine was developed from attenuated polio virus that Sabin had received from Koprowski.

Rabies Vaccine

In addition to his work on the polio vaccine, Koprowski (along with Stanley Plotkin and Tadeusz Wiktor) did significant work on an improved vaccine against rabies.[11] He developed the HDCV rabies vaccine in the 1960s at the Wistar Institute. It was licensed for use in the United States in 1980.[14]

Affiliations

Koprowski was president of Biotechnology Foundation Laboratories, Inc, and head of the Center for Neurovirology at Thomas Jefferson University. In 2006 he was awarded a record 50th grant from the National Institutes of Health. He authored or co-authored over 875 scientific papers and co-edited several scientific journals. He served as a consultant to the World Health Organization and the Pan American Health Organization.

Honors/Legacy

Koprowski received many honorary degrees, academic honors, and national decorations, including the Order of the Lionfrom the King of Belgium, the French Order of Merit for Research and Invention, a Fulbright Scholarship, and appointment as Alexander von Humboldt Professor at the Max Planck Institute for Biochemistry in Munich. In 1989 he received the San Marino Award for Medicine and the Nicolaus Copernicus Medal of the Polish Academy of Sciences in Warsaw.

Koprowski received numerous honors in Philadelphia, including the Philadelphia Cancer Research Award, the John Scott Award and, in May 1990, the most prestigious honor of his home city, the Philadelphia Award. He was a Fellow of the College of Physicians of Philadelphia, which in 1959 presented him with its Alvarenga Prize.

Koprowski was a member of the National Academy of Sciences, the American Academy of Arts and Sciences, the New York Academy of Sciences, and the Polish Institute of Arts and Sciences of America.[15] He held foreign membership in the Yugoslav Academy of Sciences and Arts, the Polish Academy of Sciences, the Russian Academy of Medical Sciences, and the Finnish Society of Sciences and Letters.

On June 3, 1983, Koprowski received an honorary doctorate from the Faculty of Medicine at Uppsala University, Sweden.[16]

On 22 March 1995, Koprowski was made a Commander of Finland's Order of the Lion by Finland's president. On 13 March 1997 he received the Legion d'Honneur from the French government. On 29 September 1998 he was presented by Poland's president with the Grand Cross of Poland's Order of Merit.

On 25 February 2000 Koprowski was honored with a reception at Philadelphia's Thomas Jefferson University celebrating the 50th anniversary of the first administration of his oral polio vaccine. At the reception, he received commendations from the United States Senate, the Pennsylvania Senate, and Pennsylvania Governor Tom Ridge.

On 13 September 2004, Koprowski was presented with the Pioneer in NeuroVirology Award by the International Society for NeuroVirology at the 6th International Symposium on NeuroVirology held in Sardinia. On 1 May 2007, Koprowski was awarded the Albert Sabin Gold Medal by the Sabin Vaccine Institute in Baltimore, Maryland.[17]

In 2014 Drexel University established the Hilary Koprowski Prize in Neurovirology in honor of Dr. Koprowski's contributions to the field of neurovirology. The prize is awarded annually in conjunction with the International Symposium on Molecular Medicine and Infectious Disease, which is sponsored by the Institute for Molecular Medicine and Infectious Disease (IMMID) within the Drexel University College of Medicine. During the Symposium, the prize recipient is asked to deliver an honorary lecture.

AIDS accusation

Main article: Oral polio vaccine AIDS hypothesis

British journalist Edward Hooper publicized a hypothesis that Koprowski's research into a polio vaccine in the Belgian Congo in the late 1950s might have caused AIDS.

The OPV AIDS hypothesis has, however, been rejected within much of the medical community and is contradicted by at least one article in the journal Nature, which claims the HIV-1 group M virus originated in Africa 30 years before the OPV trials were conducted.[1] However, the field work within the study was limited to just 34 samples all taken within the immediate vicinity of Kisangani. Despite this the journal Science refuted Hooper's claims, writing: "[I]t can be stated with almost complete certainty that the large polio vaccine trial... was not the origin of AIDS."[18]

Koprowski rejected the claim, based on his own analysis. In a separate court case, he won a regretful clarification,[19] and a symbolic award of $1 in damages, [20] in a defamation suit against Rolling Stone, which had published an article repeating similar unproven allegations.[21] A concurrent defamation lawsuit that Koprowski brought against the Associated Press was settled several years later; the settlement's terms were not publicly disclosed.[20]

Koprowski's original reports from 1960 to 1961 detailing part of his vaccination campaign in the Belgian Congo are available online from the World Health Organization.[22][23][24]

2013 (April 20, 2021): NYTimes : "Hilary Koprowski, Who Developed First Live-Virus Polio Vaccine, Dies at 96"

By Margalit Fox , April 20, 2013 / Source : [HN01L3][GDrive]

It was a brew to rival any in “Macbeth.” The main ingredients were rat brain and a fearsome, carefully cultivated virus.

In his laboratory in Pearl River, N.Y., 20 miles north of Manhattan, Dr. Hilary Koprowski macerated the ingredients in an ordinary kitchen blender one January day in 1948. He poured the result — thick, cold, gray and greasy — into a beaker, lifted it to his lips and drank. It tasted, he later said, like cod liver oil.

With that sip, Dr. Koprowski, a virologist who died on April 11 at 96, inoculated himself against polio, years before the vaccines of Jonas Salk and Albert Sabin.

Dr. Koprowski was one of the world’s foremost biomedical researchers, helping usher in a spate of innovations, including a safer, less painful and more effective rabies vaccine that remains widely used.

But his most noteworthy innovation — developing the first viable vaccine against polio and testing it successfully on humans — is far less well known. It has long been eclipsed in public memory by the triumphs of Salk, whose injectable vaccine was introduced in 1955, and Sabin, whose oral vaccine was introduced in stages in the early 1960s.

“Koprowski’s was the first serious scientific attempt at a live-virus polio vaccine,” said the historian David M. Oshinsky, whose 2005 book, “Polio: An American Story,” chronicles the race to pre-empt the disease. “Jonas Salk is a god in America, Albert Sabin’s got a ton of publicity, and Hilary Koprowski, who really should be part of that trinity, is the forgotten man.”

From the beginning, a live-virus vaccine like Dr. Koprowski’s was the most coveted weapon in the war on polio. Such vaccines can be administered orally and are far cheaper than injections. And because they involve live viruses, which can spread within a community, they can also confer immunity on others. (The Salk vaccine, made from killed viruses, cannot.)

But there was a grave catch: for a live polio vaccine to be safe, the viruses would have to be sufficiently weakened — attenuated, in medical parlance — so they would produce antibodies without inducing polio’s neurological effects.

On the evidence, the Koprowski vaccine did precisely this. But though it was given to patients overseas with good results, it was never approved for use in the United States.

Dr. Koprowski was the last of the three great virologists who stalked polio at midcentury; Sabin died in 1993, Salk in 1995. His death raises a large retrospective question: Why, in an era when a polio vaccine was the most urgently sought grail in American public health, did his go unused?

The answer, gleaned from period news accounts, histories of the war on polio and interviews with Dr. Koprowski’s associates, illuminates the delicate balance of risk and reward — and the uneasy confluence of science, politics and personality — that can inform the development of a drug.

Dr. Koprowski, who spent more than 30 years as the director of the Wistar Institute, a biomedical research center in Philadelphia, was widely described as a titanic, sometimes polarizing figure: a refugee from Nazi-occupied Poland, he was a trained concert pianist, a fluent speaker of seven languages, a connoisseur of food and wine, and a collector of old master paintings.

“He was the single most forceful, dominant, charismatic person I have ever met in my life,” said Dr. Paul A. Offit, the chief of infectious diseases at Children’s Hospital of Philadelphia, who worked under Dr. Koprowski at Wistar in the 1980s.

That outsize personality, combined with Dr. Koprowski’s outsider status — he spent part of his career in industry at a time when academia had far more prestige — may have played a role in the fate of his vaccine, his biographer, Roger Vaughan, and Professor Oshinsky said in interviews.

Others, including Dr. Offit, say the outcome was based on science alone. But all agree that Dr. Koprowski, by demonstrating that a live-virus polio vaccine could be safe and effective, paved the way for the [**Dr. Albert Bruce Sabin (born 1906)**] vaccine.

And it was [**Dr. Albert Bruce Sabin (born 1906)**]'s vaccine, even more than Salk’s, that brought about the near-eradication of polio worldwide.

“Sometimes,” Dr. Koprowski says tellingly in Mr. Vaughan’s biography, “Listen to the Music: The Life of Hilary Koprowski” (2000), “I introduce myself as the developer of the Sabin poliomyelitis vaccine.”

Hilary Koprowski was born in Warsaw on Dec. 5, 1916. He attended the Warsaw Conservatory and Warsaw University simultaneously, earning a medical degree from the university in 1939.

Late that year, after the German invasion of Poland, Dr. Koprowski, who was partly of Jewish extraction, left the country with his family. He studied music in Rome before moving to Rio de Janeiro, where he worked for the Rockefeller Foundation’s Yellow Fever Research Service.

In 1944, Dr. Koprowski arrived in the United States and joined Lederle Laboratories, a pharmaceutical concern in Pearl River. It was there, in the late 1940s, that he began his work on polio.

By the mid-20th century, the United States was reporting 20,000 to 60,000 new cases of polio a year, most affecting children. In 1938, President Franklin D. Roosevelt, who had contracted polio as an adult, established what became the March of Dimes, which would finance the Salk and [**Dr. Albert Bruce Sabin (born 1906)**] vaccines.

“What you have to understand about Koprowski was that he was the leading polio researcher from private industry,” Professor Oshinsky said. “Had he come out of the university and had he been funded by the March of Dimes, I think he would have been a favorite of the virology community.”

But he seemed, at least at times, to roil that community, already skittish about polio.

In the 1930s, researchers had tested two vaccines made from killed polio viruses, in principle safer than live ones. But as it transpired, the viruses had not been killed entirely, and the vaccines paralyzed some children.

As a result, the idea of testing a polio vaccine — much less a live one — on humans was almost beyond contemplation by midcentury.

The first successful live-virus vaccine of any kind was for yellow fever, developed in the late 1930s by the virologist Max Theiler; for his work, he received the 1951 Nobel Prize in Physiology or Medicine.

The method Theiler devised for attenuating the virus involved injecting it into a series of nonhuman embryo cells, including those of mice and chickens. In the late ’40s, Dr. Koprowski wondered whether a similar method could be used to attenuate polio.

Because the cotton rat, a genus found in the Americas, was susceptible to polio, Dr. Koprowski injected the virus into cotton rat brains.

“The thinking is this,” Dr. Offit explained: “As the virus gets better and better at growing in, in this case, a rodent, it would become less and less capable of growing or reproducing itself in people.”

The result was the grim gray cocktail Dr. Koprowski drank in the lab that day in 1948. He suffered no ill effects.

Two years later, Dr. Koprowski received a call from Letchworth Village, a home for mentally disabled children in Rockland County, N.Y. Fearing an outbreak of polio, the home asked him to vaccinate its children.

In February 1950, in the first human trial of a live polio vaccine, Dr. Koprowski vaccinated 20 children there. At the time, approval from the federal

government was required to market drugs but not to test them.

Seventeen of the children developed antibodies against polio. (The other three turned out to have the antibodies already.) None of the children experienced complications.

Describing his trial at a scientific meeting the next year, Dr. Koprowski met with astonished displeasure. In an exchange recounted in Professor Oshinsky's book, Sabin, who was present, accosted him, saying: "Why did you do it? Why? Why?"

Sabin's objection was not to Dr. Koprowski's testing the vaccine on cognitively disabled children — that was common practice then. It was to his having tested a live polio vaccine on any human being at all.

"Koprowski replied that someone had to take the next step," Professor Oshinsky wrote, "so it might as well be him."

In 1958, Dr. Koprowski administered his vaccine to nearly a quarter million patients in the Belgian Congo. "It appears to have been completely safe, almost 100 percent effective," Time magazine reported.

(His work in the Congo came to renewed attention in the 1990s after two publications — Rolling Stone magazine and "The River," a book by the British writer Edward Hooper — asserted that Dr. Koprowski had unwittingly spread H.I.V., the virus that causes AIDS, by injecting patients there with contaminated polio vaccines. The assertions have since been discredited.)

In 1960, after several live attenuated polio vaccines, including Sabin's and Dr. Koprowski's, had been studied, the United States surgeon general, Leroy E. Burney, announced the approval of Sabin's. Tests on monkeys had shown it to be somewhat more attenuated, and therefore somewhat safer, than Dr. Koprowski's.

"He believed they exaggerated the deficiencies and the dangers of his vaccine," Professor Oshinsky said of Dr. Koprowski. "Hilary Koprowski's rebuttal to Sabin would have been, 'If you had started your vaccine when I started, in the late 1940s, there would be tens of thousands of kids who are not paralyzed now.' "

At Wistar, which he led from 1957 to 1991, Dr. Koprowski is credited with transforming the place from a moribund Victorian institution into a first-class research facility. Several important vaccines were created there under his stewardship, including one for rubella, developed in the 1960s by Stanley Plotkin.

Besides his own work on the improved rabies vaccine, which he helped develop in the '60s, Dr. Koprowski was known for significant early work on the therapeutic use of monoclonal antibodies.

Occurring naturally in the body, these antibodies help the immune system attack particular kinds of cells. Made in quantity in the laboratory, they can be used to combat a range of infectious diseases, as well as certain cancers.

Dr. Koprowski, who held faculty positions at the University of Pennsylvania, with which Wistar is associated, was later affiliated with Thomas Jefferson University in Philadelphia.

Dr. Koprowski's wife, the former Irena Grasberg, whom he married in 1938, died last year. He is survived by two sons, both of whom received his vaccine as children without complications — Christopher, who confirmed his father's death, at his home in Wynnewood, Pa., and Claude — and by five grandchildren and three great-grandchildren.

Asked publicly about the lack of recognition for his polio vaccine, Dr. Koprowski was courtly, saying the corresponding lack of hoopla freed him to focus on pure research.

His private feelings differed.

"I think that there was a great deal of hurt and jealousy on his part that he never got credit for what he discovered, and for the path that he blazed for others to follow," Professor Oshinsky said. "He pretty much told me that when I interviewed him."

Dr. Koprowski received many laurels, including the French Legion of Honor. In 2007, his work was recognized with a signal honor, presented annually for distinguished contributions to vaccinology.

The award is known as the Albert B. Sabin Gold Medal.

LATENT OR DORMANT VIRAL INFECTIONS

By Hilary Koprowski
Lederle Laboratories Division, American Cyanamid Company, Pearl River, New York

The purpose of this paper is to review some of our knowledge concerning latent virus infections, in the hope that such a survey of the distribution, variety and behavior of these infections may facilitate the study of the neoplastic processes in man and in domestic and laboratory animals. I shall purposely avoid giving a definition of latency, since, if a broad, ecological view of the phenomenon of survival of parasites in nature is taken, it becomes clear that the stabilization of the host-parasite relationship cannot be based only upon the multiplication of virus at the expense of destroyed cells. It is much more probable that, in many instances, a latent virus persists in its host-cell as an innocuous symbiont, with a capacity to shed virulent variants only in rare cases.[1] Thus, if the broader view is adopted, a paper on latency of viruses should really encompass all known viral infections of plants, animals and insects. This would obviously be much beyond the scope of this presentation. Therefore, following a brief discussion of the methods of detection of dormant viral infection, examples of only a few such infections will be described in detail and the others mentioned briefly.

Detection of Latent Infection. An inapparent infection may become apparent and cause signs of disease in its host whenever the delicate equilibrium between parasite and host is upset. This may be caused by a change in environmental conditions, by a disturbance of the physiologic equilibrium of the host, or by any other factor or factors of a nature as yet undetermined.

More commonly, a dormant virus infection may be detected by a careful examination of either animal or plant tissues, the cells of which are suspected to contain these viruses. If the latter is visible and morphologically identifiable, then such methods as electron microscopy can be used successfully for that purpose. In other instances, transplantation of the material into other animal or plant species, with resulting signs of infection, may constitute proof of latency. The demonstration of a specific antigen in the suspected tissue by serological tests may sometimes be the means of detecting an inapparent viral infection.

Finally, if the latent virus is able to evoke an immune reaction in its host, detection of specific antibodies and/or resistance to reinfection with the homologous agent may be considered as an indication of persistence of the virus in inapparent form in the host.

Obviously, these methods and techniques are neither exact nor exhaustive but they cannot be improved until our knowledge of the intricate mechanism of infection of living cells with viruses becomes more comprehensive. There seems to be little doubt, however, that many instances of latent infection escape notice because of the inadequacy of existing methods of detection. These reservations should be borne in mind during the ensuing discussion.

Page 963 : [HP005Z][GDrive]

Latent Viral Infections of Mammals. In a discussion of latency of viruses, herpes simplex and rabies infections represent two contrasting problems in the extreme. Herpes simplex is a classical example of latent infection in man. The virus is dormant in the majority of human beings[2] and there are many flaring factors which may provoke the quiescent virus to appear. They may be listed as fever (induced or due to infection), cold, menstruation, exposure to sun, and, last but not least, emotional upset.[3]

Conversely, our knowledge of possible latency in rabies is very slight, and it is obvious that an answer based solely on observations in man would be inadequate. It should be pointed out, however, that circumstances surrounding the transition from the inapparent to the apparent infection in rabies may tend to incriminate certain factors. Intensive Pasteur treatment, for instance, was associated with shorter incubation periods of the disease[4] and emotional shock was thought to precipitate an attack of rabies in an exposed individual.[5] One case, that of a young boy bitten by a rabid dog, possibly merits detailed description. After exposure, the boy received

the full course of antirabies vaccine treatment and showed no signs of illness. Five months later, he became ill with bacterial pneumonia and while recovering began to exhibit signs of involvement of the central nervous system and later died of rabies.[6] Although coincidence of a prolonged incubation period cannot be ruled out in this case, the circumstantial evidence seems to demonstrate that the upset of the rabies virus-host cell equilibrium was caused by a febrile disease.

Evidence of viral latency in herpes simplex and rabies infections may be obtained in laboratory animals. Rabbits remained well, after either intramuscular or intravenous inoculation with herpes virus, but subjection to either anaphylactic or histamine shock invariably precipitated a severe encephalitis in the inoculated animals, and herpes virus could be demonstrated in the brain tissue. Characteristic pathological changes observed in the shocked animals were lacking in the control animals.[7, 8]

In the case of rabies, injection of Syrian hamsters seemed to provide a possible clue to the mechanism of its latency. When exposure to street virus was followed 24 hours later by administration of rabies antiserum, the

Obviously, these methods and techniques are neither exact nor exhaustive but they cannot be improved until our knowledge of the intricate mechanism of infection of living cells with viruses becomes more comprehensive. There seems to be little doubt, however, that many instances of latent infection escape notice because of the inadequacy of existing methods of detection. These reservations should be borne in mind during the ensuing discussion. [...]

[Pages 965 - 970]

the environment. It may be observed that symptoms of infection with potato mosaic virus are suppressed at temperatures above 24°C., whereas the virus becomes manifest at temperatures below 20°C.[50] A completely reverse situation exists in the case of potato yellow dwarf virus, which will remain masked at temperatures below 16°C., but which will flare up at temperatures of 24–28°C.[51] The same conditions were observed in the case of cabbage black ring virus.[52] Holmes' masked strain of tobacco-mosaic virus was isolated from infected stems treated for various times at 34–35°C.[53] Since then, it has also been discovered that tobacco mosaic virus remains in a masked form at temperatures below 7–10°C.[54]

Occurrence of Viruses in the Course of Propagation of Tumor Tissue in Mice and Eggs. The occurrence of viruses in mice, hamsters and eggs during passages of several types of neoplastic tissue, which I will now describe, will sound as unbelievable to you as it does to me. It will be presented, however, for the sake of argument and with the hope that other laboratories will try their hand at similar experiments.

During the past three years, many attempts were made to propagate transplantable mouse tumors in the central nervous tissue of mice following the technique described years ago by Shirai.[55] In almost all instances, tumors normally propagated by the subcutaneous route were grown in the brain tissue of mice. The mice inoculated intracerebrally usually showed signs of involvement of the central nervous system on the 9th to 14th day after implantation and, on autopsy, growing neoplasms were demonstrated by histopathological examination, and on bioassay. Some of the tumors underwent passage by this technique through 50 to 80 generations. In certain instances, however, in the course of subjecting some of the tumors to passage, mice became sick three to five days after inoculation with brain tissue material stemming from the preceding passage. Careful investigation of the resulting passage indicated that a filterable agent was causing the sickness of the animals,[56] and the study was extended in order to learn more about the nature of the phenomenon.

In TABLE 7 data are summarized covering the isolation of the viruses recovered in the course of these tumor studies.* The Ridgeway osteogenic sarcoma obtained from an outside laboratory was transplanted subcutaneously in AKM mice through eight passages, and tumor suspensions then were injected intracerebrally into Swiss albino mice. These animals became sick four days later, and the recovered virus was tentatively identified, on the basis of preliminary results of neutralization tests, as being related to Ilheus virus. In order to exclude the possibility that a latent virus might have been picked up from the host mice during the eight passages in the laboratory, another attempt at intracerebral passage of neoplastic tissue was made, using fresh tumors immediately upon receiving them from the outside laboratory. These tumors were injected directly into mice by the intracerebral route. Again, the same virus was isolated.

In the case of a Wagner osteogenic sarcoma, filterable agents were isolated

* The author expresses his grateful appreciation to Dr. Alice E. Moore, of the Sloan-Kettering Institute for Cancer Research, for the mice-bearing tumors; and to Dr. Stanley Stellar, of the Department of Neurosurgery, New York School of Medicine, for the human tumors.

Page 971 : [HP0061][GDrive]

after two or three subcutaneous transplants, followed by one or two intracerebral passages. At this point, it became quite obvious that a plausible explanation of this phenomenon could be that a latent viral infection persisted in the mice of our laboratory, and that intracerebral inoculation of such a fast growing tissue as neoplasm made the infection manifest. In the next attempt, therefore, a suspension of Wagner osteogenic sarcoma propagated through four mouse passages by subcutaneous transfer was inoculated into the yolk sac of six-day-old chick embryos. The embryos were incubated at 37°C. and harvested three days later. A ten per cent embryonic suspension was injected intracerebrally into mice and underwent passage

into the yolk sac of six-day-old embryos. No signs of disease were observed in either the embryos or the mice injected with embryonic tissue, representing the first through the ninth egg passages. Embryos injected with the tenth embryo passage, however, died 48 to 72 hours after inoculation, and the inoculation of an emulsion of these into mice yielded a virus identical with that isolated by means of mouse passage. This virus, on the basis of preliminary neutralization tests, was found to be related to the West Nile, Japanese B, St. Louis, Ilheus group of viruses.

Similar results were obtained with the Patterson lymphosarcoma, except that in two passage series, the tumor was transplanted for 13 and 18 passages by the subcutaneous route in the AKM strain of mice before a filterable agent could be isolated in eggs or in mice injected intracerebrally. When

Though often cited as our most precious resource and dearest commodity, children -- particularly those institutionalized in orphanages, mental asylums, and warehouses for the "feebleminded" -- were often sought out by physicians and medical researchers as test subjects for experimentation. Even a cursory examination of 20th century medical research will illuminate numerous examples of children -- some only days old -- being incorporated in a wide range of medical research. Many prominent investigators in search of practical treatments and vaccines, exploring the impact of radiation and psychotropic drugs, or new surgical procedures like lobotomy, routinely found their way to poorly funded and under-staffed state institutions housing the nation's most vulnerable citizens.

Thomas Eugene Kurtz (born 1928)

Education Princeton University, Knox College (Mathematics)

Known for *BASIC*, *TRUE BASIC*

Awards

1974 *AFIPS Pioneer Award*

1991 *IEEE Computer Science Pioneer Award*

Thomas Eugene Kurtz (born February 22, 1928) is a retired Dartmouth professor of mathematics and computer scientist, who along with his colleague John G. Kemeny[1] set in motion the then revolutionary concept of making computers as freely available to college students as library books were, by implementing the concept of time-sharingat Dartmouth College. In his mission to allow non-expert users to interact with the computer, he co-developed the BASIC programming language (Beginners All-purpose Symbolic Instruction Code) and the Dartmouth Time Sharing System during 1963 to 1964.

A native of Oak Park, Illinois, United States, Kurtz graduated from Knox College in 1950, and was awarded a Ph.D. degree from Princeton University in 1956, where his advisor was John Tukey, and joined the Mathematics Department of Dartmouth College that same year, where he taught statistics and numerical analysis.

In 1983, Kurtz and Kemeny co-founded a company called True BASIC, Inc. to market True BASIC, an updated version of the language.

Kurtz has also served as Council Chairman and Trustee of EDUCOM, as well as Trustee and Chairman of NERComP, and on the Pierce Panel of the President's Scientific Advisory Committee. Kurtz also served on the steering committees for the CONDUIT project and the CCUC conferences on instructional computing.

In 1974, the American Federation of Information Processing Societies gave an award to Kurtz and Kemeny at the National Computer Conference for their work on BASIC and time-sharing.[2] In 1991, the Computer Society honored Kurtz with the IEEE Computer Pioneer Award[3] and in 1994 he was inducted as a Fellow of the Association for Computing Machinery.[4]

Early life and education

In 1951, Kurtz' first experience with computing came at the Summer Session of the Institute for Numerical Analysis at University of California, Los Angeles. His interests have included numerical analysis, statistics, and computer science ever since. He graduated in 1950 when he obtained his bachelor's degree majoring in mathematics and in 1956, at the age of 28, he went on to acquire his PhD from Princeton University. His thesis was on a problem of multiple comparisons in mathematical statistics.[5] Kurtz composed his first computer program in 1951 while working with computers at UCLA in the institute of numerical analysis. He performed this feat just after finishing grad school and one year into his tuition at Princeton University.

Dartmouth

In 1963 to 1964, Kurtz and Kemeny developed the first version of the Dartmouth Time-Sharing System, a time-sharing system for university use, and the BASIC language.

From 1966 to 1975, Kurtz served as Director of the Kiewit Computation Center at Dartmouth,[6] and from 1975 to 1978, Director of the Office of Academic Computing. From 1980 to 1988 Kurtz was Director of the Computer and Information Systems program at Dartmouth, a ground-breaking multidisciplinary graduate program to develop IS leaders for industry. Subsequently, Kurtz returned to teaching full-time as a Professor of Mathematics, with an emphasis on statistics and computer science.

BASIC

As part of the Dartmouth Time-Sharing System, Kemeny and Kurtz created the BASIC programming language. The very first BASIC program ran on May 1, 1964 at 4 a.m., and neither Kemeny nor Kurtz thought of this as a start to something grand. They merely hoped it would help students learn something about the computers they were using. **The pair made certain that their invention was immediately dispersed to the public and made no real money from it.** Dartmouth College copyrighted BASIC; however it made BASIC available and free to anyone wanting to use it. The name for the language originated from Kurtz's wish to have a simple acronym that meant something as well. Kurtz states that, "We wanted a word that was simple but not simple-minded, and BASIC was that one."[7] **BASIC along with the books published on it earned a lot of positive feedback, f**or example: "This second edition of Basic Programming gives a thorough description of BASIC, which is useful not only for the beginner, but also for the more experienced programmer."; " My overall evaluation of BASIC programming is that it is ideal for the individual who wishes to program with a minimum of effort and of equal value for group or classroom instruction." [8]

The theme that BASIC was for the average computer user is stressed by Kurtz. In an open letter he reiterates upon past statements that BASIC was invented to give students a simple programming language that was easy to learn, as all the current languages of the time were dedicated to professionals. He then went on to say that BASIC was for people who did not want to dedicate their lives to programming.[9] The repetition of this idea by Kurtz accentuates that even through all of his success the language he wrote would remain implemented for the masses and not just specialists.

BASIC standards were created in the 1980s for the ECMA, and ANSI with their versions being released in 1986 and 1987 respectively.[10] **BASIC popularity skyrocketed in 1975 after a pair of youngsters in a Harvard dormitory, Bill Gates and Paul Allen, created a version of BASIC that was viable on one of the earliest personal computers. G**ates and Allen's version became the most prominent iterations of BASIC.

Influence

The road to BASIC itself was a long one. **Kemeny and Kurtz had forged DARSIMCO – Dartmouth Simplified Code – Dartmouth's inaugural attempt at making a computing language in 1956; however DARSIMCO soon became obsolete when the language FORTRAN manifested itself**. In 1962 Kemeny and a Dartmouth undergraduate, Sidney Marshall, created the language DOPE, Dartmouth Oversimplified Programming Experiment, which was a direct predecessor of BASIC. **DOPE itself was little used, and Kurtz preferred trying to implement successful languages such as FORTRAN and ALGOL.** Kurtz's experience with Dartmouth ALGOL 30 for the LGP-30 convinced him that devising subsets of these languages was not quite practical, and this led him to adopt Kemeny's notion of creating a new language entirely.

Critics

Although BASIC was widely regarded as a success, many computing professionals thought it was a poor choice for larger and more complicated programs. Larger programs became confusing and messy when they used the "GO TO" statement to jump from one line of a program to another. A further criticism of the original language was that it was unstructured, which made it difficult to split programs into separate parts to improve readability. BASIC not being structured also hindered the ability to debug and modify parts of the code, and this limited its use by larger companies. Hence it largely remained a language used for only smaller programs.[11]

True BASIC

In 1983, in response to a proliferation of "Street BASICs," a group of graduating Dartmouth students persuaded Kemeny and Kurtz to offer the Dartmouth version of the language as a commercial product. The first offering of their company, True Basic, Inc., was based on Dartmouth BASIC 7, which featured modern programming constructs such as "IF..THEN..ELSE, DO..LOOP and EXIT DO".[12] The company described its product as "Simple. Elegant. Powerful. True BASIC." Upon Kemeny's advice, True BASIC was not limited to a single OS or computer system. "Today versions of True BASIC are available for DOS, Mac OS, Windows, Unix, and Linux systems".[13] When Kurtz retired from Dartmouth College in 1993, he continued to develop and maintain True Basic.

---

Bio on Thomas E. Kurts - from IEEE / Computer History Museum

Source : [HI0018][GDrive]

Born February 22, 1928, Oak Park, Ill.; with John Kemeny, developer of the programming language and system BASIC.

Education: BA, Knox College, *1950*; PhD, mathematics/statistics, Princeton University, 1956.

Professional Experience: Dartmouth College: instructor, mathematics, 1956-1958, assistant professor, 1958-1963, associate professor, 1963-1966; professor, 1966-1993, director, Computing Center, 1959-1975, director, Kiewit Computation Center, 1966-1975, director, Office of Academic Computing, 1975-1978, vice chair and chair, Program in Computing and Information Science, 1979-1988; member, Pierce Panel, President's Science Advisory Council in Higher Education, 1965-1967; chairman, Council, EDUCOM, 1973-1974.

Honors and Awards: AFIPS Pioneer Award, 1974; DSc (Hon.), Knox College, 1987; IEEE Computer Science Pioneer Award, 1991.

Kurtz received his PhD in statistics from Princeton in 1956, his first contact with computing having occurred in 1951 at the summer session of the Institute for Numerical Analysis (INA) at UCLA in the summer of 1951. He joined the Dartmouth College Mathematics Department (chaired by John G. Kemeny) in 1956 as an instructor. Besides teaching statistics and numerical analysis, he served as the Dartmouth contact to the New England Regional Computer Center (NERComP), which was supported in part by IBM at MIT. In 1959 Dartmouth obtained an LGP-30 computer, and Kurtz became the first director of Dartmouth's computing center.

Around 1962, Kurtz and John G. Kemeny began jointly to supervise the design and development of a time-sharing system for university use. **The idea to use time-sharing to reach all Dartmouth students came from John McCarthy who, around 1961, advised, "you guys ought to do time-sharing."** This effort culminated in 1964 in the first Dartmouth Time-Sharing System (DTSS). Although o**ther languages such as Fortran and Algol were provided, the principal language was BASIC, which was deliberately designed to be easy to learn and easy to use.**

Subsequently, **Kurtz served as the director of the Kiewit Computation Center from 1966 to 1975, and as director of the Office of Academic Computing from 1975 to 1978.** In 1979 he and Stephen J. Garland organized a professional master's program in Computer and Information Systems, funded in part with a grant from IBM. Upon termination of the CIS program in 1988, Kurtz returned to teaching. He retired from Dartmouth College in 1993.

Outside of Dartmouth, Kurtz served as council chairman and trustee of EDUCOM, as trustee and chairman of NERcomP, and on the so-called Pierce Panel of the President's Advisory Committee. **He also served on the steering committee for two NSF- and ARPA-supported activities**, and was the chair of the first CCUC conference on instructional computing. **He helped form the American National Standards committee X3J2, which developed the ANSI standard for BASIC, serving as chair from 1974 to 1985,** and as secretary from 1990 to the present. He is a member of the ISO committee SC22/WG8, concerned with the international standard for BASIC, and served as its convener from 1987 to 1993.

In 1983, he joined John Kemeny and three former Dartmouth students in forming True BASIC, Inc., whose purpose was to develop quality educational software and a platform-independent BASIC compiler based on the ANSI standard. He continues to be associated with this company, and serves as its secretary/ treasurer.

QUOTATION

"If Fortran is the lingua franca, then certainly it must be true that BASIC is the lingua playpen."

Sir Patrick Playfair Laidlaw FRS FRCP (28 September 1881 – 19 March 1940) was a Scottish virologist.

Biography

Laidlaw was born in Glasgow, the son of Robert Laidlaw, M.D., at that time Superintendent of the Glasgow Medical Mission.[1] He was educated at Leys School, Cambridge and St. John's College, Cambridge.

From 1920–23, he studied the properties of histamine at the Wellcome Physiological Research Laboratories after which he went to Guy's Hospital as a lecturer in experimental pathology. As a virologist at the Medical Research Council in 1922 his researches on dog-distemper led to two ways of immunisation against it, which achievement earned him the award of a Royal Medal by the Royal Society in 1933. In 1927 he had been elected a fellow of the Royal Society.[2]

He was one of the scientists working at the Medical Research Council (NIMR Farm Laboratories) at Mill Hill who first isolated influenza virus from humans.[3] This happened when ferrets they were working on to develop a distemper vaccine caught influenza from one of the scientists in the laboratory.

He was knighted in the 1935 Birthday Honours for distinguished service to medical science.[4]

He died unmarried at the age of 58.

Historical Profile: Sir Patrick Playfair Laidlaw

British virologist who first isolated the influenza virus from human beings. Born in Glasgow, UK, on Sept 26, 1881, he died on March 19, 1940, aged 59 years.

Described as a gentle, modest, generous man of science, Sir Patrick Playfair Laidlaw was part of the team of researchers who in 1933 discovered that a virus was the infective agent of human influenza, a deadly respiratory illness that had killed more than 50 million people only 15 years previously. The 1918 pandemic stands as the most deadly single event in recorded history, killing more people than did the Black Death bubonic plague (1347–51) or World War 1. While presenting Laidlaw with the Royal Medal in 1933, the President of the Royal Society, Sir Frederick Gowland Hopkins, stated that "both in its scientific and practical aspects, this is one of the most successful investigations in medical science".

Laidlaw studied medicine at St John's College, Cambridge, and graduated from Guy's Hospital, London, where he received the Gold Medal in Medicine for showing distinguished promise. His next 4 years were spent at the Wellcome Physiological Research Laboratories at Herne Hill in south London, researching pharmacological actions of aminoacids under the directorship of Henry Hallett Dale, who described Laidlaw's time there as one of "remarkable and varied fertility in research". This was a happy time for Laidlaw— he would spend summers playing golf, and visit his beloved Scotland for fishing and sailing. In 1913, Laidlaw received the Sir William Dunn Lectureship in Pathology at Guy's; however, this bright prospect was overshadowed by the start of World War 1. The war years were a bleak time for scientists in Britain, and few achievements could be made in research between 1914 and 1918. Unable to fight because of a childhood disability, for Laidlaw, this was also a time of isolation.

In 1918–19, a deadly influenza swept through Britain. Influenza is a severe respiratory disease with a fast onset—some victims died within hours of their fi rst symptoms, which included pneumonia, heliotrope cyanosis (a term coined during the 1918 fl u pandemic to describe the blue discolouration of the skin caused by buildup of fluid in the lungs and subsequent suffocation), and sepsis. Little was known about the cause of influenza, and no effective prevention, vaccine, or treatments were available. **There were suggestions that the pandemic was the result of German biological warfare, or that the war was a predisposing cause, related to mustard gas, smoke, cordite fumes, and filthy trenches, explains Carole Reeves, Senior Lecturer at the UCL Department of Science and Technology Studies (London, UK). "There was a paradox; Britain, with one of the most sophisticated public health systems of the period, mounted one of the least effective responses to the pandemic", Reeves comments.** Methods of prevention and treatment ranged from nasal douching and gauze masks to opium, alcohol, and turtle soup. "The most common preventive advice was for the public to ignore the epidemic and let expert medical professionals and public health authorities use science to deal with it", she explains. "The pandemic was arguably the first major challenge to laboratory bacteriology and the new scientific medicine was unable to provide a convincing and widely acceptable frame for the disease."

During this crisis of confidence in the British medical profession, the National Institute for Medical Research (NIMR) launched an initiative in 1922 to create a programme of researchers in an unexplored area— infections caused by filterable or ultramicroscopic viruses. Laidlaw, then at the Medical Research Council (MRC) at Mill Hill, London, was chosen to join the team. This was the longest, last, and most important period in his life as a researcher, during which he was elected as a Fellow of the Royal Society in 1927. **In 1933, an outbreak of typical, epidemic influenza presented a chance for Laidlaw to test the possibility that an infection could be caused by a filterable virus.** "The work by Sir Patrick Laidlaw and his colleagues Wilson Smith, and later Sir Christopher Andrewes, on influenza can be classified as a key event in influenza research", explains John McCauley, Director of the WHO Influenza Centre at the MRC. The discovery was made when ferrets they were working on to develop a distemper vaccine caught influenza from one of the scientists in the laboratory. At this time, the systematic study of virus diseases was at an early stage, and as McCauley explains: "Until this truly revolutionary work that enabled the team to show that the agent of influenza was a virus and, crucially in so doing, how it could be propagated, influenza research was largely observational." The team's breakthrough enabled definitive research to be done on the properties of the virus, the discovery of its now notorious antigenic variation, and the characterisation of the immune response to infection, which combined led to the rapid development of influenza vaccines. McCauley points out that the ferret model developed by Laidlaw for his work on canine distemper virus and used for his investigations into influenza is still used for influenza research today. He also adds that although alternative laboratory animals, such as mice and guinea pig models, have been developed, none replicate the disease in human beings as well as the ferret model developed by Laidlaw.

In 1935, Laidlaw received an Honour of Knighthood, and, 1 year later, became Deputy Director of the NIMR. His final years were spent quietly (he gave only two lectures that came to publication), but in varied collaborations in entirely diff erent specialties. As Dale remarked: "Few men have given so freely of their knowledge and their ideas to assist the researches of others, and still fewer have been able to do so with effect over such a remarkable range of scientific problems." Laidlaw will be remembered as a dedicated researcher who boosted scientific credibility at a time when many had lost faith in the medical community, and revolutionised our understanding of a deadly virus, saving millions of lives and paving the way for further developments in infl uenza research and treatment. - Natalie Harrison

2016 (Sep) - History and evolution of influenza control through vaccination: from the first monovalent vaccine to universal vaccines

Summary

Influenza is a highly infectious airborne disease with an important epidemiological and societal burden; annual epidemics and pandemics have occurred since ancient times, causing tens of millions of deaths. A hundred years after this virus was first isolated, influenza vaccines are an important influenza prevention strategy and the preparations used display good safety and tolerability profiles. Innovative tools, such as recombinant technologies and intra-dermal devices, are currently being investigated in order to improve the immunological response. The recurring mutations of influenza strains has prompted the recent introduction of a quadrivalent inactivated vaccine. In the near future, scientific research will strive to produce a long-lasting universal vaccine containing an antigen that will offer protection against all influenza virus strains.

Introduction

Influenza viruses are negative-sense, single-stranded RNA viruses belonging to the Orthomyxoviridae family, together with Isavirus, Thogotovirus and Quaranjavirus. Three types of influenza viruses, namely influenza A, B and C, are capable of determining epidemics and pandemics in humans, with influenza A being the most common circulating type and causing significant illness, being most prone to antigenic shifts and the more likely type to lead to a pandemic [1, 2]. Recently, a new genus (termed influenza virus D) has been discovered in pigs and cattle with influenza-like illness syndrome in the United States [3, 4] and in Europe [5].

Influenza is a highly infectious airborne disease that affects a significant percentage of the world's population; local annual epidemics and pandemics have occurred since ancient times, causing tens of millions of deaths [6].

A history of influenza: from the classical period to the nineteenth century

In 412 BC, in the "Book of Epidemics", Hippocrates described a putative influenza-like illness syndrome called "fever of Perinthus" or "cough of Perinthus" [7]. While some scholars claim that this is probably the first historical description of influenza (a winter and a spring epidemic of an upper respiratory tract infection occurring regularly every year at Perinthus, a port-town in Marmaraereglisi, a northern part of Greece, now Turkey), others, including the notable 19th-century editor of Hippocrates, Émile Littré (1801-1881), think that a diagnosis of diphtheria would better fit the description of complications (pneumonia, fits of coughing and wheezing, angina and paralysis of soft palate and limbs). On the other hand, symptoms such as disturbed vision and night blindness suggest a combination of diseases, including deficiency syndromes (e.g. vitamin A deficiency) [8]. In the years 1173 and 1500, two other influenza outbreaks were described, though in scant detail [9-11]. The name "influenza" originated in the 15th century in Italy, from an epidemic attributed to the "influence of the stars", which, according to Ginctrac, raged across Europe and perhaps in Asia and Africa [12].

It seems that influenza also reached the Americas. Scholars and historians debate whether influenza was already present in the New World or whether it was carried by contaminated pigs transported on ships. Some Aztec texts speak of a "pestilential catarrh" outbreak in 1450-1456 in an area now corresponding to Mexico, but these manuscripts are difficult to interpret correctly and this hypothesis seems controversial [13].

The first reliable documents regarding influenza-like illness syndrome date from 1510, when the virus spread from Africa to Europe. The first pandemic, or worldwide epidemic, occurred in 1557, though some scholars deny that it really was an outbreak of influenza. The first pandemic/ worldwide epidemic that undoubtedly fits the description of influenza appeared in 1580, beginning in Asia and Russia and spreading to Europe via Asia Minor and North-West Africa. In Rome, it caused the death of over 8,000 people, while in Spain it decimated the populations of entire cities. Subsequently, it also affected the Americas [14].

Over the centuries, other pandemics were described worldwide. From 1404 to the middle of the 19th century, 31 influenza epidemics were recorded, including eight large-scale pandemics. Subsequently, others appeared, including three in the 20th century [14]. Some of the most notable outbreaks occurred in 1729, in 1781-1782 (a pandemic spreading from China to Russia, Europe and North America), in 1830-1833 (a pandemic which again spread from China to India, the Philippines, Indonesia, Russia, Europe and North America), in 1847-1848, and in 1898-1900 (spreading from Europe to India, Australia, and North and South America) [14].

One of the most devastating was the pandemic of "Spanish" influenza in 1918–1919, which caused an estimated 21 million deaths worldwide and was defined by Waring as "the greatest medical holocaust in history" [14, 15].

At the end of the 19th century, the etiology of this disease had yet not been well clarified; it was believed that the disease, termed "winter catarrh", was caused by bacteria (the so-called bacterial hypothesis), such as pneumococcus, streptococcus or Haemophilus influenzae. This latter was also named Bacillus influenzae or Pfeiffer's bacillus, after Richard Pfeiffer (1858-1945), who described it during the 1889-1892 influenza epidemic. This bacillus had already been discovered by the Polish microbiologist Bujwid Odo Feliks Kazimierz (1857- 1942) in biopsy material a year earlier [16].

In the same period, the French microbiologists Charles Nicolle (1866-1936), Charles Lébally and René Dujarric de la Rivière (1885-1969) of the Pasteur Institute showed that the flu pathogen could pass through a fine filter. However, despite their brilliant experiments, the viral hypothesis continued to be neglected until the virus was isolated [16, 17].

In 1889, some Spanish doctors believed that influenza was a variant of dengue fever, whilst others attributed influenza outbreaks to a variety of causes including cannon fire on the western front, the building of the Madrid underground, air pollution, sunspots, or the spread of the habit of smoking poor-quality tobacco [18].

The thirties: virus isolation and the first experimental vaccines

During the 1918-1919 pandemic, some scientists began to suspect that bacteria were not the real agent of influenza disease. **One of these was the scholar [Dr. Richard Edwin Shope (born 1901)], who deeply investigated swine flu in 1920.** However, it was only in 1932-1933 that the English scientists Wilson Smith (1897-1965), Sir Christopher Andrewes (1896-1988) and **Sir Patrick Laidlaw (1881-1940),** working at the Medical Research Council at Mill Hill, first isolated the influenza A virus from nasal secretions of infected patients, thereby demonstrating the intranasal human transmission of this virus [19, 20]. A few years later, the American virologist and epidemiologist Thomas Francis Junior (1900-1969) and Smith, in England, were able to transmit the virus to mice [21]. Subsequently, in 1935, Sir Frank Macfarlane Burnet (1899-1985) and Smith separately discovered that the flu virus could be grown on the chorio-allantoid membrane of embryonated hens' eggs [22], and in 1936 the first neutralized antibodies generated by infection by human influenza virus were isolated [23].

In the next five years, important developments took place: the demonstration that the virus inactivated by formalin was immunogenic in humans, purification of the virus by means of high-speed centrifugation, and the discovery that the influenza virus grew easily in fertilized hen eggs, a procedure that is still used today to manufacture most influenza vaccines [23].

The first clinical trials of influenza vaccines were conducted in the mid-1930s [24, 25].

A study by Smith, Andrewes and Stuart-Harris was conducted among military forces in England in 1937 using a subcutaneous vaccination with an inactivated strain isolated from a mouse lung [25].

In 1938, Francis, together with Jonas Edward Salk (1914-1995), managed to protect USA military forces. Salk would subsequently use this successful experience to develop an effective polio vaccine in 1952 [26, 27].

The forties: inactivated influenza vaccines

Influenza vaccination had two main objectives: (i) to protect against disease, and (ii) to achieve a high vaccination rate in order to ensure protection in unvaccinated people. The first vaccine was an inactivated, monovalent preparation which only contained a subtype of the influenza A virus [26, 27].

In December 1942, large studies were begun to be conducted on the first influenza virus vaccines; these provided the first official proof that inactivated influenza vaccines could yield effective protection against flu epidemics [28].

The efficacy and safety of inactivated vaccines were first studied between 1942 and 1945; in the meantime, a new strain of flu virus was discovered, the influenza virus type B, which is the main cause of seasonal epidemics, as was the phenomenon of so-called "influenza mismatch". Influenza mismatch is caused by major and minor mutations of circulating viruses. As a result, the virus contained in the vaccine does not match the circulating strain, determining a reduction in the effectiveness of subtype A influenza vaccines.

A new route of influenza immunization was tested in December 1942, with the subcutaneous inactivated bivalent vaccine containing viruses of type A and type B. The following years, the first bivalent vaccine was licensed in the United States and became available for use in the general population [29, 30].

The fifties: influenza mismatch and influenza surveillance

The first system for the surveillance of circulating influenza virus strains in several countries worldwide was created in 1952 by the World Health Organization (WHO) in order to monitor the various virus mismatches reported. This important innovative tool enabled the composition of seasonal influenza vaccines to be determined on the basis of the epidemiology of influenza in the previous season [31]. In 1946, as a result of viral mutation, a new variant of influenza A (H1N1), A/FM/1/47, appeared in Australia. This gave rise to a new influenza subtype, the H2N2 strain, which caused the pandemic known as Asian flu [32].

The following year, the US Commission on Influenza recommended that a representative of this strain be included in subsequent vaccines.

The emergence of an HA subtype different from those circulating in previous seasons determined the need for pandemic influenza vaccines [31].

The sixties: split vaccines

New inactivated compounds were tested for safety and efficacy during seasonal epidemics in the 1960s, in particular two new formulations were created: split and subunit vaccines. The 1968 pandemic led to the development of trivalent inactivated vaccines (TIVs) against influenza viruses; moreover the development of new split or subunit vaccines led to a decrease of adverse reactions in children. These vaccines were split using ether and/or detergent, and haemagglutinin and neuraminidase were, in the case of subunit vaccines, purified and enriched [33].

In the same period, the first flu vaccines were licensed in Europe, while in the US annual influenza vaccination was recommended for individuals at major risk of influenza complications.

In 1968, the new virus strain H3N2 (Hong Kong) appeared, completely replacing the previous type A strain (H2N2, or Asian influenza), and led to another global pandemic with high morbidity and mortality [34]. In the same year, a new type of vaccine, the split vaccine, was authorized in the US after several clinical studies had demonstrated that it was less reactogenic than whole virus vaccines, especially in the early years of life [35].

The seventies: genetic reassortment

Split vaccines were widely used during the pandemic swine influenza in 1976 and in 1977, when the H1N1 subtype re-emerged worldwide. However, they were seen to be less immunogenic than whole virus vaccines in "primed" subjects who had never been vaccinated. Indeed, it was shown that two vaccine doses were needed in order to ensure effective protection [36].

At the beginning of the 1970s, an important innovation was introduced into the production of influenza vaccines: the genetic reassortment of influenza virus strains; this technique enabled the vaccine strains to grow faster in embryonated hen eggs [37].

The first subunit vaccine was created between 1976 and 1977. This contained only the surface antigens, hemagglutinin (HA) and neuraminidase (NA), which were isolated by means of successive purification steps.

This innovative tool proved to be highly immunogenic and well tolerated in humans, especially in children, although two doses were needed to guarantee vaccine effectiveness during epidemics [38].

The eighties: subunit vaccines

In 1980, the first subunit vaccines were licensed in the United Kingdom and are currently available in several countries worldwide.

In 1978, as a result of a major mutation, a new virus strain, H1N1, appeared on the global epidemiological scene. This strain, which was similar to a virus circulating in 1958, emerged in Russia and began to co-circulate, either simultaneously or alternately, with the previous one [39].

Antigenic drift, caused by frequent changes in the composition of the virus, determined the need to update the vaccine composition each year. This necessity prompted both the implementation of the first surveillance systems and the production of the first trivalent vaccine, which included three formulation strains (one strain of influenza A/ H1N1, an influenza virus A /H3N2 and a type B virus), in order to ensure effective protection during the 1978 pandemic.

Live attenuated influenza vaccines

In the period 1935-1941, the first clinical trials involving live attenuated influenza vaccines were conducted. The efficacy of these seasonal vaccines was guaranteed by the correspondence between the circulating strain and the strain contained in the vaccine and by the virus dose grown in hen egg embryos [34].

In 1944, Stanley described in detail the preparation and properties of an influenza virus vaccine produced in embryonated hen eggs; this vaccine was concentrated and purified by means of differential centrifugation and inactivated by means of various procedures [23].

In 1949, an important change in vaccine development involved the introduction of the use of cell cultures for virus growth.

In 1997,the so-called "avian flu" pandemic broke out in Hong Kong. This was caused by influenza virus A/ H5N1, a highly pathogenic strain.

In order to contain this pandemic, the techniques of genetic rearrangement developed in those years enabled a huge number of vaccine doses to be produced in a short time by applying recombinant DNA technology to the influenza A/H5N1 virus [34].

Recent years

In recent years, scientific research developed new techniques of immunization, which may be more immunogenic and better tolerated during administration, thereby reducing adverse events. In 2003, for instance, the FDA in the United States authorized the use of an intranasally administered live attenuated vaccine, called FluMist®, in adults [40]. In the 2003-2004 influenza season, an outbreak in Asia was caused by an influenza A/H5N1 strain. This was later used to produce a vaccine, which was licensed in the United States by the FDA in 2007.

More recent years saw the development of adjuvanted vaccines, such as those containing alum adjuvants and the oil in water adjuvant MF-59, which significantly enhanced antigenicity [6].

Specifically, MF-59-adjuvanted vaccines were used in the elderly and in young children, and proved to elicit a good response even to pandemic strains with which subjects had not been primed by natural influenza infection. Similar responses were obtained through the use of other emulsions, such as stable emulsion (SE) and AS03, which were included in the 2009 pandemic influenza vaccines [36].

In the most recent pandemic season (2009), the influenza virus H1N1, which was transmitted to humans by pigs, was estimated to have caused more than 200,000 deaths in the first 12 months of its circulation [41].

A massive effort to produce vaccine for the new H1N1 strain began shortly after scientists identified the virus. The virus proved to grow slowly during the manufacturing process, which relies on cultivation of the virus in chicken eggs. Because of manufacturing delay, the vaccine was available in most countries after the second peak of influenza cases at the end of October leaving most people not immunized while influenza H1N1 virus was circulating [42].

In the elderly, the vaccine efficacy normally decreases, because of immunosenescence. For this reason, in 2009 the Advisory Committee on Immunization Practices (ACIP) recommended and authorized the use of high-dose Fluzone ®, a new formulation containing a 4-fold higher HA dose than the traditional trivalent vaccine [43].

In 2011, as a result of developments in research into new vaccine delivery techniques, the FDA first authorized the intradermal administration of Fluzone®. This new route of administration involved antigen-presenting cells (APCs) in the dermis; these cells process antigens for subsequent presentation in the lymphoid organs, resulting in the stimulation of both innate and adaptive immunity. The intradermal vaccines elicited a better immunological response than intramuscular vaccines, particularly in the elderly; in healthy adults, it yielded an immune response comparable to that elicited by the traditional vaccines, while saving on the HA dose [44-48]. In 2012, the FDA approved Fluarix®, the first quadrivalent vaccine in the United States. This split vaccine contained two influenza A strains and two influenza B antigens. The presence of an additional influenza B strain reduced the possibility of a mismatch between the circulating viruses and the vaccine composition, while maintaining the same immunogenicity and safety as standard trivalent vaccines [49].

In 2013, the FDA approved FluBlock®, a recombinant trivalent influenza vaccine, for use in people aged between 18 and 49 years. FluBlock® was licensed in a spray formulation and was the first trivalent influenza vaccine made by using recombinant DNA technology. Derived from Baculovirus, it contained a 3-fold higher HA dose than traditional trivalent vaccines [50, 51]. The scale-up potential of the insect cell/baculovirus vector system may offer advantages in terms of rapid antigen change and response to a pandemic situation [31].

Currently, scientists are exploring the fascinating prospect of developing a universal vaccine by exploiting T-cells and by attempting to elicit broadly neutralizing antibodies. Moreover, efforts are being made to design M2e- or stalk-based vaccines, since these proteins (the type-2 matrix protein and the stalk domain of HA, respectively) are quite well conserved from an evolutionary standpoint [52, 53].

Conclusions

In the hundred years since the influenza virus was isolated, influenza vaccine preparations have evolved to ensure effective protection, while maintaining a good safety and tolerability profile.

The recurring mutations of influenza strains prompted the introduction of a quadrivalent inactivated vaccine, the composition of which is determined on the basis of the most frequent strains isolated in the previous season during continuous surveillance by the WHO.

Current research priorities include the development of a universal influenza vaccine that could offer protection against all influenza virus strains, thereby overcoming the challenges faced due to antigenic drift and shift or of co-circulation of different viral strains. Another important priority is to identify sustainable vaccine production platforms capable of rapidly meeting the large global demands for influenza vaccine in the face of an influenza pandemic.

Lyndon Hermyle LaRouche Jr. (born 1922)

Wikipedia Lyndon LaRouche

2019 (Feb 13) - NY Times : "Lyndon LaRouche, cult figure, dies at 96

Source : [HN012D][GDrive]

[HN012E][GDrive]

Lyndon H. LaRouche Jr. speaking at a news conference in Trenton in 1984 in advance of the New Jersey primary as he sought the Democratic presidential nomination. It was one of his eight campaigns for the White House as a fringe candidate.

Lyndon LaRouche, the quixotic, apocalyptic leader of a cultlike political organization who ran for president eight times, once from a prison cell, died on Tuesday. He was 96.

His death was announced on the website of his organization, La Rouche/Pac. The statement did not specify a cause or say where he died.

Defining what Mr. LaRouche stood for was no easy task. He began his political career on the far left and ended it on the far right. He said he admired Benjamin Franklin, Alexander Hamilton, Abraham Lincoln and Ronald Reagan and loathed Hitler, the composer Richard Wagner and other anti-Semites, though he himself made anti-Semitic statements.

He was fascinated with physics and mathematics, particularly geometry, but called concerns about climate change “a scientific fraud.”

He condemned modern music as a tool of invidious conspiracies — he saw rock as a particularly British one — and found universal organizing principles in the music of Bach, Beethoven and Mozart.

Some called him a case study in paranoia and bigotry, his mild demeanor notwithstanding. One biographer, Dennis King, in “Lyndon LaRouche and the New

American Fascism" (1989), maintained that Mr. LaRouche and his followers were a danger to democratic institutions.

Mr. LaRouche denigrated a panoply of ethnic groups and organized religions. He railed against the "Eastern Establishment" and environmentalists, who he said were trying to wipe out the human race. Queen Elizabeth II of England was plotting to have him killed, he said. Jews had surreptitiously founded the Ku Klux Klan, he said. He described Native Americans as "lower beasts."

Even so, Mr. LaRouche was able to develop alliances with farmers, the Nation of Islam, teamsters, abortion opponents and Klan adherents. Acolytes kept Mr. LaRouche's political machine going by peddling his tracts and magazines in airports, and by persuading relatives and friends to donate large sums to help him fight his designated enemies.

He operated through a dizzying array of front groups, among them the National Democratic Policy Committee, through which he received millions of dollars in federal matching money in his recurring presidential campaigns. His forces also sponsored candidates at the state and local levels, including for school board seats.

His movement attracted national attention, especially in 1986, when two LaRouche followers, Mark Fairchild and Janice Hart, unexpectedly won the Democratic nomination for lieutenant governor and secretary of state, respectively, in Illinois.

Adlai E. Stevenson III, the Democratic candidate for governor of Illinois that year, was appalled. He denounced the LaRouche group as "neo-Nazis" and refused to run with Mr. Fairchild and Ms. Hart, organizing a third-party bid instead. He, as well as the LaRouche supporters, lost to James R. Thompson, the Republican incumbent.

Some voters said they had voted for Mr. Fairchild and Ms. Hart because they had been endorsed by Mr. LaRouche's National Democratic Policy Committee, which they thought was affiliated with the mainstream Democratic Party.

Critics of Mr. LaRouche said he had used that committee to deceive people abroad as well. In 1982, he managed to arrange a meeting with President José López Portillo of Mexico, evidently because Mexican officials thought Mr. LaRouche represented the Democratic Party.

"I'm as American as apple pie," Mr. LaRouche once said.

Whatever he was, he received thousands of votes in his campaigns for president. In 1980, he outpolled Gov. Jerry Brown of California by a thousand votes in the Democratic presidential primary in Connecticut. In 1986, the candidates fielded by his National Democratic Policy Committee received 20 to 40 percent of the vote in local elections in California, Idaho, Illinois, Indiana, Massachusetts, New Hampshire, Ohio, Pennsylvania and Texas.

Lyndon Hermyle LaRouche Jr. was born on Sept. 8, 1922, in Rochester, N.H., to Lyndon and Jesse (Weir) LaRouche. He grew up in the Quaker tradition. His father was a traveling salesman for the United States Shoe Machinery Corporation, and his mother once ran a Quaker meeting in Boston's Back Bay.

His was not a happy childhood. Boys would pick on him, he said, but he refused to fight them, which only brought more disapprobation.

It got no better after the family moved to Lynn, Mass. He regarded himself there as an outcast and had few friends in high school. He was not an "ugly duckling," he said, "but a nasty duckling."

When World War II began, Mr. LaRouche declared himself a conscientious objector, citing his pacifist Quaker upbringing. But toward the end of the war he enlisted in the Army, despite his mother's objections.

After the war, he enrolled in Northeastern University in Boston but "resigned," he said, because the university was not challenging his superior intellect. He said he had been able to become the century's leading economist without formal college study.

He married Janice Neuberger in the early 1950s and had a son, Daniel, by her in 1956. The marriage failed, and he never talked publicly about his son and his former wife in his later years.

Mr. LaRouche's political roots were Marxist. From 1948 to 1963, he was active in the Socialist Workers Party, a Trotskyite group.

His own group surfaced during the student unrest at Columbia University in the late 1960s as a faction of the left-wing Students for a Democratic Society. It evolved into the National Caucus of Labor Committees, an organization largely made up of young upper-middle-class people who espoused Mr. LaRouche's Marxist views.

He first ran for president in 1976 as the candidate of the left-wing United States Labor Party, now defunct.

By then, though, his politics had already begun moving to the right. And after spending much time in West Germany, he returned with right-wing, anti-Semitic views. Many of his followers made the shift with him.

George Johnson, the author of "Architects of Fear: Conspiracy Theories and Paranoia in American Politics" (1983), wrote that Mr. LaRouche had developed a conspiracy theory that stretched back to the beginnings of civilization.

"In the world according to LaRouche," Mr. Johnson wrote, "history is a war between the Platonists (the good guys) and the evil Aristotelians. Anyone who has taken Philosophy 101 can follow the drift: Platonists believe in standards, an absolute truth that can be divined by philosopher kings like Mr. LaRouche. To the Aristotelians everything is relative."

In Mr. LaRouche's view, Mr. Johnson continued, "true Platonists believe that industrialization, technology and classical music should be used to bring wealth and enlightenment to the citizens of the world."

He added: "The Aristotelians are trying to stop them by using not only sex, drugs and rock 'n' roll but also environmentalism and quantum theory. With their bag of brainwashing techniques, they hope to trick civilization into destroying itself, bringing on a new dark ages in which the world's riches will be firmly in the hands of the oligarchs."

Mr. LaRouche's views became the foundation of a political movement. By the mid-1970s, his organization had 37 offices in North America and 26 in Europe and Latin America. A core membership in the United States numbered about 1,000. One follower won 27 percent of the vote in a local election in Seattle. Mr. LaRouche was pulling in enough money nationally to qualify for federal matching funds for his presidential campaigns.

He had also become an entrepreneur, starting three companies, one of which printed newspapers for high schools; together they brought in revenues of $5 million or more a year.

In his efforts to build a worldwide organization, Mr. LaRouche was helped by his wife, Helga Zepp-LaRouche, a native of Germany who had been a journalist there. Information about his survivors was not immediately available.

Mr. LaRouche was at the apex of his power in the mid-1980s, when he moved his headquarters to a large rented estate in Northern Virginia, in Round Hill, outside Leesburg. When neighbors wondered aloud why he had turned the estate into an armed camp, rigged with electronic security and patrolled by men with semiautomatic rifles, Mr. LaRouche went on the attack. He said that the Leesburg Garden Club was “a nest of Soviet fellow travelers.”

In 1987, after an F.B.I. investigation, Mr. LaRouche was convicted in Virginia on charges of scheming to defraud the Internal Revenue Service and of deliberately defaulting on more than $30 million in loans from thousands of his supporters. He was sentenced to 15 years in prison and sent to a federal penitentiary in Minnesota.

The conviction hurt his movement but did not end it. He was released from prison in 1994, after serving a third of his sentence. He immediately announced that he would run for president in 1996. He ran again in 2000 and 2004. After Barack Obama was elected in 2008, Mr. LaRouche warned that the new president was in “grave and imminent danger” of being assassinated by the “British Empire,” a familiar target of Mr. LaRouche’s.

By 2015 he had long turned against Mr. Obama, calling for his impeachment and accusing him in one instance of orchestrating Turkey’s downing of a Russian fighter jet involved in the war in Syria. “Obama organized an act of war, and has thus endangered the United States, as well as all of humanity,” Mr. LaRouche wrote.

But he could be bipartisan in his attacks. He accused the Bush family of collaborating with Nazi Germany during World War II, and said that the invasion of Iraq in 2003 was a product of a neoconservative conspiracy, led by Vice President Dick Cheney, to deceive the American people. That view was expressed in a series of pamphlets, titled “Children of Satan.”

But Mr. LaRouche was heartened by the election of President Trump, though he perceived a British conspiratorial hand reaching into the United States to foment efforts to “politically paralyze” the president and bring about his impeachment.

That would be a mistake, he said. As his website declared, “Not since William McKinley has a president been so clear in his intent to return the nation to the economic tradition of Alexander Hamilton, to end the policies of British imperial free trade, and make a full commitment to industry, manufacturing, scientific advancement and world peace.

Father

Lyndon H. LaRouche

Lyndon Hermyle LaRouche Jr. (September 8, 1922 – February 12, 2019) was an American political activist, convicted fraudster, cult leader, and founder of the LaRouche movement, whose main organization was the National Caucus of Labor Committees (NCLC).[1][2][3][4]

Born in Rochester, New Hampshire, LaRouche became sympathetic to socialist and Marxist movements and ideals in his twenties during World War Two and by the 1960s became engaged in increasingly smaller and more radical splinter groups. During the 1970s he created the foundation of the LaRouche Movement and became more engaged in conspiratorial beliefs and violent and/or illegal activities. In 1986, his movement reached its height in electoral success when Larouchite candidates won several Democratic primaries for state offices in Illinois. (The defeated mainstream Democratic candidates ran in the general election as members of the Illinois Solidarity Party; the Larouchite Democrats all finished a distant third.) Later in the 1980s, criminal investigations led to convictions of several LaRouche movement members, including LaRouche himself. He was sentenced to fifteen years imprisonment, but only served five years.

LaRouche was a perennial candidate for President of the United States. He ran in every election from 1976 to 2004 as a candidate of third parties established by members of his movement. He also tried to gain the Democratic presidential nomination. In 1996, he got 5% of the total nationwide vote in Democratic primaries. In 2000, he received enough primary votes to qualify for delegates in some states, but ultimately was refused those delegates at the convention.

Early life

LaRouche was born in Rochester, New Hampshire, the oldest of three children of Jessie Lenore (née Weir) and Lyndon H. LaRouche, Sr.[5] His paternal grandfather's family emigrated to the United States from Rimouski, Quebec, whereas his maternal grandfather was born in Scotland.[6] His father worked for the United Shoe Machinery Corporation in Rochester before the family moved to Lynn, Massachusetts.[7]

His parents became Quakers after his father converted from Catholicism. They forbade him from fighting with other children, even in self-defence, which he said led to "years of hell" from bullies at school. As a result, he spent much of his time alone, taking long walks through the woods and identifying in his mind with great philosophers. He wrote that, between the ages of twelve and fourteen, he read philosophy extensively, embracing the ideas of Leibniz and rejecting those of Hume, Bacon, Hobbes, Locke, Berkeley, Rousseau, and Kant.[8][9][10][11] He graduated from Lynn English High School in 1940. In the same year, the Lynn Quakers expelled his father from the group, for reportedly accusing other Quakers of misusing funds, while writing under the pen name Hezekiah Micajah Jones. LaRouche and his mother resigned in sympathy for his father.[12][13][14]

University studies, Marxism, marriage

LaRouche attended Northeastern University in Boston and left in 1942. He later wrote that his teachers "lacked the competence to teach me on conditions I was willing to tolerate".[15] As a Quaker, he was a conscientious objector (CO) during World War II and joined a Civilian Public Service camp.[16] In 1944 he joined the United States Army as a non-combatant and served in India and Burma with medical units. He ultimately worked as an ordnance clerk at the end of the war. He described his decision to serve as one of the most important of his life.[17] While in India he developed sympathy for the Indian independence movement. LaRouche wrote that many GIs feared they would be asked to support British forces in actions against Indian independence forces and characterized that prospect as "revolting to most of us".[18]

He discussed Marxism in the CO camp, and while traveling home on the SS *General Bradley* in 1946, he met Don Merrill, a fellow soldier, also from Lynn, who converted him to Trotskyism. Back in the U.S., he resumed his education at Northeastern University. He returned to Lynn in 1948 and the next year joined the Socialist Workers Party (SWP), adopting the name "Lyn Marcus" for his political work.[19] He arrived in New York City in 1953, where he worked as a management consultant.[20] In 1954 he married Janice Neuberger, a psychiatrist[*citation needed*] and member of the SWP. Their son, Daniel, was born in 1956.[21]

Career

1960s

Teaching and the National Caucus of Labor Committees

Further information: National Caucus of Labor Committees

Twenty to thirty students would ... sit on the floor surrounding LaRouche, who now sported a very shaggy beard ... LaRouche gave them esoteric assignments, such as searching through the writings of Georges Sorel to discover Rudd's anarchistic origins, or studying Rosa Luxemburg's *The Accumulation of Capital*.

—Tim Wohlforth[22]

By 1961 the LaRouches were living on Central Park West in Manhattan, and LaRouche's activities were mostly focused on his career and not on the SWP. He and his wife separated in 1963, and he moved into a Greenwich Village apartment with another SWP member, Carol Schnitzer, also known as Larrabee.[23] In 1964 he began an association with an SWP faction called the Revolutionary Tendency, a faction which was later expelled from the SWP, and came under

the influence of British Trotskyist leader Gerry Healy.[24]

For six months, LaRouche worked with American Healyite leader Tim Wohlforth, who later wrote that LaRouche had a "gargantuan ego", and "a marvelous ability to place any world happening in a larger context, which seemed to give the event additional meaning, but his thinking was schematic, lacking factual detail and depth." Leaving Wohlforth's group, LaRouche briefly joined the rival Spartacist League before announcing his intention to build a new Fifth International.[22]

In 1967 LaRouche began teaching classes on Marx's dialectical materialism at New York City's Free School,[25][self-published source] and attracted a group of students from Columbia University and the City College of New York, recommending that they read *Das Kapital*, as well as Hegel, Kant, and Leibniz. During the 1968 Columbia University protests, he organized his supporters under the name *National Caucus of Labor Committees* (NCLC).[25] The aim of the NCLC was to win control of the Students for a Democratic Society branch—the university's main activist group—and build a political alliance between students, local residents, organized labor, and the Columbia faculty.[26][27][28][29] By 1973 the NCLC had over 600 members in 25 cities—including West Berlin and Stockholm—and produced what LaRouche's biographer, Dennis King, called the most literate of the far-left papers, *New Solidarity*.[30][31] The NCLC's internal activities became highly regimented over the next few years. Members gave up their jobs and devoted themselves to the group and its leader, believing it would soon take control of America's trade unions and overthrow the government.[32][33][34]

1970s

1971: Intelligence network

Further information: LaRouche movement

Robert J. Alexander writes that LaRouche first established an NCLC "intelligence network" in 1971. Members all over the world would send information to NCLC headquarters, which would distribute the information via briefings and other publications. LaRouche organized the network as a series of news services and magazines, which critics say was done to gain access to government officials under press cover.[35] The publications included *Executive Intelligence Review*, founded in 1974. Other periodicals under his aegis included; *New Solidarity*, *Fusion Magazine*, *21st Century Science and Technology*, and *Campaigner Magazine*. His news services and publishers included American System Publications, Campaigner Publications, New Solidarity International Press Service, and The New Benjamin Franklin House Publishing Company. LaRouche acknowledged in 1980 that his followers impersonated reporters and others, saying it had to be done for his security.[36] In 1982, *U.S. News and World Report* sued New Solidarity International Press Service and Campaigner Publications for damages, alleging that members were impersonating its reporters in phone calls.[37]

U.S. sources told *The Washington Post* in 1985 that the LaRouche organization had assembled a worldwide network of government and military contacts, and that his researchers sometimes supplied information to government officials. Bobby Ray Inman, the CIA's deputy director in 1981 and 1982, said LaRouche and his wife had visited him, offering information about the West German Green Party. A CIA spokesman said LaRouche met Deputy Director John McMahon in 1983 to discuss one of LaRouche's trips overseas. An aide to Deputy Secretary of State William Clark said when LaRouche's associates discussed technology or economics, they made good sense and seemed to be qualified. Norman Bailey, formerly with the National Security Council, said in 1984 that LaRouche's staff comprised "one of the best private intelligence services in the world. ... They do know a lot of people around the world. They do get to talk to prime ministers and presidents." Several government officials feared a security leak from the government's ties with the movement.[38] According to critics, the supposed behind-the-scenes processes were more often flights of fancy than inside information. Douglas Foster wrote in *Mother Jones* in 1982 that the briefings consisted of disinformation, "hate-filled" material about enemies, phony letters, intimidation, fake newspaper articles, and dirty tricks campaigns.[39] Opponents were accused of being gay or Nazis, or were linked to murders, which the movement called "psywar techniques".[40][41]

From the 1970s through to the first decade of the 21st century, LaRouche founded several groups and companies. In addition to the National Caucus of Labor Committees, there was the Citizens Electoral Council (Australia), the National Democratic Policy Committee, the Fusion Energy Foundation, and the U.S. Labor Party. In 1984 he founded the Schiller Institute in Germany with his second wife, and three political parties there—the *Europäische Arbeiterpartei*, *Patrioten für Deutschland*, and *Bürgerrechtsbewegung Solidarität*—and in 2000 the Worldwide LaRouche Youth Movement. His printing services included Computron Technologies, Computype, World Composition Services, and PMR Printing Company, Inc, or PMR Associates.[42]

1973: Political shift; "Operation Mop-Up"

A 1973 internal FBI letter, noting the Communist Party's efforts to eliminate LaRouche, and suggesting submission of a "blind memorandum" to the Communist Party's newspaper.

LaRouche wrote in his 1987 autobiography that violent altercations had begun in 1969 between his NCLC members and several New Left groups when Mark Rudd's faction began assaulting LaRouche's faction at Columbia University.[43] Press accounts alleged that between April and September 1973, during what LaRouche called "Operation Mop-Up", NCLC members began physically attacking members of leftist groups that LaRouche classified as "left-protofascists"; an editorial in LaRouche's *New Solidarity* said of the Communist Party that the movement "must dispose of this stinking corpse."[44][45][46] Armed with chains, bats, and martial-art nunchuksticks, NCLC members assaulted Communist Party, SWP, and Progressive Labor Party members and Black Power activists on the streets and during meetings. At least 60 assaults were reported. The operation ended when police arrested several of LaRouche's followers; there were no convictions, and LaRouche maintained they had acted in self-defense. Journalist and LaRouche biographer Dennis King writes that the FBI may have tried to aggravate the strife, using measures such as anonymous mailings, to keep the groups at each other's throats.[47][48][49][50][51][52] LaRouche said he met representatives of the Soviet Union at the United Nations in 1974 and 1975 to discuss attacks by the Communist Party USA on the NCLC and to propose a merger, but said he received no assistance from them.[53] One FBI memo, obtained under the Freedom of Information Act, proposes assisting the CPUSA in an investigation "for the purpose of ultimately eliminating him [LaRouche] and the threat of the NCLC." (see image to left)

LaRouche's critics such as Dennis King and Antony Lerman allege that in 1973 and with little warning, LaRouche adopted more extreme ideas, a process accompanied by a campaign of violence against his opponents on the left, and the development of conspiracy theories and paranoia about his personal safety.[54] According to these accounts, he began to believe he was under threat of assassination from the Soviet Union, the CIA, Libya, drug dealers, and bankers.[55] He also established a "Biological Holocaust Task Force," which, according to LaRouche, analyzed the public health consequences of International Monetary Fund (IMF) austerity policies toward impoverished nations in Africa, and predicted that epidemics of cholera as well as possibly entirely new diseases would strike Africa in the 1980s.[56][57]

1973: U.S. Labor Party

Further information: U.S. Labor Party

LaRouche founded the U.S. Labor Party in 1973 as the political arm of the NCLC.[58][59] At first the party was "preaching Marxist revolution", but by 1977 they shifted from left-wing to right-wing politics.[60] A two-part article in *The New York Times* in 1979 by Howard Blum and Paul L. Montgomery alleged that LaRouche had turned the party (at that point with 1,000 members in 37 offices in North America, and 26 in Europe and Latin America) into an extreme-right, antisemitic organization, despite the presence of Jewish members. LaRouche denied the newspaper's charges, and said he had filed a $100 million libel suit; his press secretary said the articles were intended to "set up a credible climate for an assassination hit."[61]

The *Times* alleged that members had taken courses in how to use knives and rifles; that a farm in upstate New York had been used for guerrilla training; and that several members had undergone a six-day anti-terrorist training course run by Mitchell WerBell III, an arms dealer and former member of the Office of Strategic Services, who said he had ties to the CIA. Journalists and publications the party regarded as unfriendly were harassed, and it published a list of potential assassins it saw as a threat. LaRouche expected members to devote themselves entirely to the party, and place their savings and possessions at its disposal, as well as take out loans on its behalf. Party officials would decide who each member should live with, and if someone left the movement, his remaining partner was expected to live separately from him. LaRouche would question spouses about their partner's sexual habits, the *Times* said, and in one case reportedly ordered a member to stop having sex with his wife, because it was making him "politically impotent."[62][63][64]

1973: "Ego-stripping" and "brainwashing" allegations

LaRouche began writing in 1973 about the use of certain psychological techniques on recruits. In an article called "Beyond Psychoanalysis", he wrote that a worker's persona had to be stripped away to arrive at a state he called "little me," from which it would be possible to "rebuild their personalities around a new socialist identity," according to *The Washington Post*.[65][66] *The New York Times* wrote that the first such session—which LaRouche called "ego-stripping"—involved a German member, Konstantin George, in the summer of 1973. LaRouche said that during the session he discovered that a plot to assassinate him had been implanted in George's mind.[67]

He recorded sessions with a 26-year-old British member, Chris White, who had moved to England with LaRouche's former partner, Carol Schnitzer. In December 1973 LaRouche asked the couple to return to the U.S. His followers sent tapes of the subsequent sessions with White to *The New York Times*as evidence of an assassination plot. According to the *Times*, "[t]here are sounds of weeping, and vomiting on the tapes, and Mr. White complains of being deprived of sleep, food and cigarettes. At one point someone says 'raise the voltage', but (LaRouche) says this was associated with the bright lights used in the questioning rather than an electric shock." The *Times* wrote, "Mr. White complains of a terrible pain in his arm, then LaRouche can be heard saying, 'That's not real. That's in the program.'" LaRouche told the newspaper White had been "reduced to an eight-cycle infinite loop with look-up table, with homosexual bestiality." He said White had not been harmed and that a physician—a LaRouche movement member—had been present throughout.[67][68] White ended up telling LaRouche he had been programmed by the CIA and British intelligence to set up LaRouche for assassination by Cuban exile frogmen.[69]

According to *The Washington Post*, "brainwashing hysteria" took hold of the movement. One activist said he attended meetings where members were writhing on the floor saying they needed de-programming.[15] In two weeks in January 1974, the group issued 41 separate press releases about brainwashing. One activist, Alice Weitzman, expressed skepticism about the claims.[70]

1974: Contacts with far right groups, intelligence gathering

LaRouche established contacts with Willis Carto's Liberty Lobby and elements of the Ku Klux Klan in 1974.[71] Frank Donner and Randall Rothenbergwrote that he made successful overtures to the Liberty Lobby and George Wallace's American Independent Party, adding that the "racist" policies of LaRouche's U.S. Labor Party endeared it to members of the Ku Klux Klan.[72] George Michael, in *Willis Carto and the American Far Right*, says that LaRouche shared with the Liberty Lobby's Willis Carto an antipathy towards the Rockefeller family.[73] The Liberty Lobby defended its alliance with LaRouche by saying the U.S. Labor Party had been able to "confuse, disorient, and disunify the Left."[73]

Gregory Rose, a former chief of counter-intelligence for LaRouche who became an FBI informant in 1973, said that while the LaRouche movement had extensive links to the Liberty Lobby, there was also copious evidence of a connection to the Soviet Union. George and Wilcox say neither connection amounted to much—they assert that LaRouche was "definitely not a Soviet agent" and state that while the contact with the Liberty Lobby is often used to imply "'links' and 'ties' between LaRouche and the extreme right," it was in fact transient and marked by mutual suspicion. The Liberty Lobby soon pronounced itself disillusioned with LaRouche, citing his movement's adherence to "basic socialist positions" and his softness on "the major Zionistgroups" as fundamental points of difference. According to George and Wilcox, American neo-Nazi leaders expressed misgivings over the number of Jews and members of other minority groups in his organization, and did not consider LaRouche an ally.[74] George Johnson, in *Architects of Fear*, similarly states that LaRouche's overtures to far right groups were pragmatic rather than sincere. A 1975 party memo spoke of uniting with these groups only to overthrow the established order, adding that once that goal had been accomplished, "eliminating our right-wing opposition will be comparatively easy."[75]

Howard Blum wrote in *The New York Times* that, from 1976 onwards, party members sent reports to the FBI and local police regarding members of left-wing organizations. In 1977, he wrote, commercial reports on U.S. anti-apartheid groups were prepared by LaRouche members for the South African government, student dissidents were reported to the Shah of Iran's Savak secret police, and the anti-nuclear movement was investigated on behalf of power companies. Johnson says the intelligence network was made up of "obnoxious devotees commandeering WATS lines and tricking bureaucrats into giving them information."[76] By the late 1970s, members were exchanging almost daily information with Roy Frankhouser, a government informant and infiltrator of both far right and far left groups who was involved with the Ku Klux Klan and the American Nazi Party.[77][78][79][80] The LaRouche organization believed Frankhouser to be a federal agent who had been assigned to infiltrate right-wing and left-wing groups, and that he had evidence that these groups were actually being manipulated or controlled by the FBI and other agencies.[81][82] LaRouche and his associates considered Frankhouser to be a valuable intelligence contact, and took his links to extremist groups to be a cover for his intelligence work.[77][83][84] Frankhouser played into these expectations, misrepresenting himself as a conduit for communications to LaRouche from "Mr. Ed", an alleged CIA contact who did not exist in reality.[77][85]

Blum wrote, at around this time, that LaRouche's Computron Technologies Corporation included Mobil Oil and Citibank among its clients, that his World Composition Services had one of the most advanced typesetting complexes in the city and had the Ford Foundation among its clients, and that his PMR Associates produced the party's publications and some high school newspapers.[84]

Around the same time, according to Blum, LaRouche was telling his membership several times a year that he was being targeted for assassination, including by the Queen of the United Kingdom, Zionist mobsters, the Council on Foreign Relations, the Justice Department, and the Mossad.[84]LaRouche sued the City of New York in 1974, saying that CIA and British spies had brainwashed his associates into killing him.[86] According to *The Patriot-News* of Harrisburg, Pennsylvania, LaRouche said he had been "threatened by Communists, Zionists, narcotics gangsters, the Rockefellers and international terrorists."[87] LaRouche later said that,

"Since late 1973, I have been repeatedly the target of serious assassination threats and my wife has been three times the target of attempted

assassination. ... My enemies are the circles of McGeorge Bundy, Henry Kissinger, Soviet President Yuri Andropov, W. Averell Harriman, certain powerful bankers, and the Socialist and Nazi Internationals, as well as international drug traffickers, Colonel Gadaffi, Ayatollah Khomeini, and the Malthusian lobby."[88]

1975–1976: presidential campaign

Further information: Lyndon LaRouche U.S. presidential campaigns and Views of Lyndon LaRouche and the LaRouche movement § LaRouche's campaign platforms

In 1975 Clarence M. Kelley, FBI Director, called the NCLC a "violence-oriented organization."[89]

In March 1975 Clarence M. Kelley, director of the FBI, testified before the House Appropriations Committee that LaRouche's NCLC was "a violence-oriented organization of 'revolutionary socialists' with a membership of nearly 1,000 in chapters in some 50 cities." He said that during the previous two years its members had been "involved in fights, beatings, using drugs, kidnappings, brainwashings, and at least one shooting. They are reported to be armed, to have received defensive training such as karate, and to attend cadre schools and training schools to learn military tactics."[89]

In 1975, under the name *Lyn Marcus*, LaRouche published *Dialectical Economics: An Introduction to Marxist Political Economy*, described by its only reviewer as "the most peculiar and idiosyncratic" introduction to economics he had ever seen. Mixing economics, history, anthropology, sociology and a surprisingly large helping of business administration, the work argued that most prominent Marxists had misunderstood Marx, and that bourgeois economics arose when philosophy took a wrong, reductionist turn under British empiricists like Locke and Hume.[90][91]

In 1976, LaRouche campaigned for the first time in a presidential election as a U.S. Labor Party candidate, polling 40,043 votes (0.05 percent). It was the first of eight consecutive presidential elections in which he took part between 1976 and 2004. It enabled him to attract $5.9 million in federal matching funds; candidates seeking their party's presidential nomination qualify for matching funds if they raise $5,000 in each of at least 20 states.[92] His platform predicted financial disaster by 1980 accompanied by famine and the virtual extinction of the human race within 15 years, and proposed a debt moratorium; nationalization of banks; government investment in industry especially in the aerospace sector, and an "International Development Bank" to facilitate higher food production.[93]When Legionnaires' disease appeared in the U.S. that year, he said it was a continuation of the swine flu outbreak, and that senators who opposed vaccination were suppressing the link as part of a "genocidal policy".[94]

His campaign included a paid half-hour television address, which allowed him to air his views before a national audience, something that became a regular feature of his later campaigns. There were protests about this, and about the involvement of the NCLC in public life generally. Writing in *The Washington Post*, Stephen Rosenfeld said LaRouche's ideas belonged to the radical right, neo-Nazi fringe, and that his main interests lay in disruption and disinformation; Rosenfeld called the NCLC one of the "chief polluters" of political democracy. Rosenfeld argued that the press should be "chary" of offering them print or air time: "A duplicitous violence-prone group with fascistic proclivities should not be presented to the public, unless there is reason to present it in those terms." LaRouche wrote in 1999 that this comment had "openly declared ... a policy of malicious lying" against him.[95]

Helga Zepp in 2005

1977: Second marriage

LaRouche married again in 1977. His wife, Helga Zepp, was then a leading activist in the West German branch of the movement. She went on to work closely with LaRouche for the rest of her career, standing for election in Germany in 1980 for his *Europäische Arbeiterpartei* (European Workers Party), and founding the Schiller Institute in Germany in 1984.[96]

1980s

National Democratic Policy Committee, "October Surprise" theory

From the autumn of 1979, the LaRouche movement conducted most of its U.S. electoral activities as the National Democratic Policy Committee (NDPC), a political action committee.[97] The name drew complaints from the Democratic Party's Democratic National Committee. Democratic Party leaders refused to recognize LaRouche as a party member, or to seat the few delegates he received in his seven primary campaigns as a Democrat.[98] His campaign platforms advocated a return to the Bretton Woods system, including a gold-based national and world monetary system; fixed exchange rates; and abolishing the International Monetary Fund.[99] He supported the replacement of the central bank system, including the U.S. Federal Reserve System, with a national bank;[100] a war on drug trafficking and prosecution of banks involved in money laundering;[101] building a tunnel under the Bering Strait; the building of nuclear power plants; and a crash program to build particle-beam weapons and lasers, including support for elements of the Strategic Defense Initiative (SDI). He opposed the Soviet Union and supported a military build-up to prepare for imminent war; supported the screening and quarantine of AIDS patients; and opposed environmentalism, deregulation, outcome-based education, and abortion.[102]

"No more will the United States fight World Wars to save the British Empire in any shape or guise. No more will the United States tolerate the British system, whether colonial or neo-colonial. No more will the United States tolerate the economics of Adam Smith in any part of the world. We are going to take this aching, poor, hungry world and we're going to transform it with American methods. We're going to transform it through the export and development of high technology, we're going to have Manhattan Projects and NASA projects and every *dirigiste*, Federally-directed, scientific crazed program that we deem necessary."

— Lyndon LaRouche, *at the opening of the National Democratic Policy Committee, 1979.*

In December 1980, LaRouche and his followers started what came to be known as the "October Surprise" allegation,[103] namely that in October 1980 Ronald Reagan's campaign staff conspired with the Iranian government during the Iran hostage crisis to delay the release of 52 American hostages held in Iran, with the aim of helping Reagan win the 1980 United States presidential election against Jimmy Carter. The Iranians had agreed to this, according to the theory, in exchange for future weapons sales from the Reagan administration. The first publication of the story was in LaRouche's *Executive Intelligence Review* on December 2, 1980, followed by his *New Solidarity* on September 2, 1983, alleging that Henry Kissinger, one of LaRouche's regular targets, had met Iran's Ayatollah Beheshti in Paris, according to Iranian sources in Paris. The theory was later echoed by former Iranian President Abolhassan Banisadr and former Naval intelligence officer and National Security Council member Gary Sick.[104]

1983: Move from New York to Loudoun County

The Washington Post wrote that LaRouche and his wife moved in August 1983 from New York to a 13-room Georgian mansion on a 250-acre section of the Woodburn Estate, near Leesburg, Loudoun County, Virginia. The property was owned at the time by a company registered in Switzerland. Companies associated with LaRouche continued to buy property in the area, including part of Leesburg's industrial park, purchased by LaRouche's Lafayette/Leesburg

associated with LaRouche continued to buy property in the area, including part of Leesburg's industrial park, purchased by LaRouche's Lafayette/Leesburg Ltd. Partnership to develop a printing plant and office complex.[105]

Neighbors said they saw LaRouche guards in camouflage clothes carrying semi-automatic weapons, and the *Post* wrote that the house had sandbag-buttressed guard posts nearby, along with metal spikes in the driveway and concrete barriers on the road. One of his aides said LaRouche was safer in Loudoun County: "The terrorist organizations which have targeted Mr. LaRouche do not have bases of operations in Virginia." LaRouche said his new home meant a shorter commute to Washington. A former associate said the move also meant his members would be more isolated from friends and family than they had been in New York.[105] According to the *Post* in 2004, local people who opposed him for any reason were accused in LaRouche publications of being commies, homosexual, drug pushers, and terrorists. He reportedly accused the Leesburg Garden Club of being a nest of Soviet sympathizers, and a local lawyer who opposed LaRouche on a zoning matter went into hiding after threatening phone calls and a death threat.[15] In leaflets supporting his application of concealed weapons permits for his bodyguards in Leesburg, Virginia, he wrote:

"I have a major personal security problem ... [Without the permits] the assassination teams of professional mercenaries now being trained in Canada and along the Mexico border may be expected to start arriving on the streets of Leesburg ... If they come, there will be many people dead or mutilated within as short an interval as 60 seconds of fire."[106]

Regarding LaRouche's paramilitary security force, armed with semi-automatic weapons,[107] a spokesperson said that they were necessary, because LaRouche was the subject of "assassination conspiracies".[108]

1984: Schiller Institute, television spots, contact with Reagan administration

Further information: Schiller Institute

Helga Zepp-LaRouche founded the Schiller Institute in Germany in 1984.[109] In the same year, LaRouche was able to raise enough money to purchase 14 television spots, at a cost of $330,000 each, in which he called Walter Mondale—the Democratic Party's presidential candidate—a Soviet agent of influence, triggering over 1,000 telephone complaints.[110] On April 19, 1986, NBC's *Saturday Night Live* aired a sketch satirizing the ads, portraying the Queen of the United Kingdom and Henry Kissinger as drug dealers. LaRouche received 78,773 votes in the 1984 presidential election.[111]

In 1984, media reports stated that LaRouche and his aides had met Reagan administration officials, including Norman Bailey, senior director of international economic affairs for the National Security Council (NSC), and Richard Morris, special assistant to William P. Clark, Jr. There were also reported contacts with the Drug Enforcement Administration, the Defense Intelligence Agency, and the CIA. The LaRouche campaign said the reporting was full of errors.[112] In 1984 two Pentagon officials spoke at a LaRouche rally in Virginia; a Defense Department spokesman said the Pentagon viewed LaRouche's group as a "conservative group ... very supportive of the administration." White House spokesman Larry Speakes said the Administration was "glad to talk to" any American citizen who might have information.[113] According to Bailey, the contacts were broken off when they became public.[32]Three years later, LaRouche blamed his criminal indictment on the NSC, saying he had been in conflict with Oliver North over LaRouche's opposition to the Nicaraguan Contras.[114] According to a LaRouche publication, a court-ordered search of North's files produced a May 1986 telex from Iran–Contradefendant General Richard Secord, discussing the gathering of information to be used against LaRouche.[115] King states that LaRouche's *Executive Intelligence Review* was the first to report on important details of the Iran–Contra affair, predicting that a major scandal was about to break months before mainstream media picked up on the story.[116]

Strategic Defense Initiative

Main article: Fusion Energy Foundation

The Wheat Building in Leesburg, Virginia, which housed the Fusion Energy Foundation in the 1980s.

The LaRouche campaign supported Reagan's Strategic Defense Initiative (SDI). Dennis King wrote that LaRouche had been speculating about space-based weaponry as early as 1975. He set up the Fusion Energy Foundation, which held conferences and tried to cultivate scientists, with some success. In 1979, FEF representatives attended a Moscow conference on laser fusion. LaRouche began to promote the use of lasers and related technologies for both military and civilian purposes, calling for a "revolution in machine tools."[117]

According to King, LaRouche's associates had for some years been in contact with members of the Reagan administration about LaRouche's space-based weapons ideas.[118] LaRouche proposed the development of defensive beam technologies as a policy that was in the interest of both the United States and the Soviet Union, as the alternative to an arms race in offensive weapons, and as a generator of spin-off economic benefits. Between February 1982 and February 1983, with the approval of the National Security Council, LaRouche met with Soviet embassy representative Evgeny Shershnev to discuss the proposal. During this period, Soviet economists also began to study LaRouche's economic forecasting model. However, following Reagan's public announcement of the SDI in March 1983, Soviet representatives broke off all contact with LaRouche and his representatives.[117]

Physicist Edward Teller, a proponent of SDI and X-ray lasers, told reporters in 1984 that he had been courted by LaRouche, but had kept his distance. LaRouche began calling his plan the "LaRouche-Teller proposal," though they had never met. Teller said LaRouche was "a poorly informed man with fantastic conceptions."[119]

LaRouche later attributed the collapse of the Soviet Union to its refusal to follow his advice to accept Reagan's offer to share the technology.[120] Former Secretary of Defense Donald Rumsfeld reported in his 2011 memoir that at a 2001 dinner in Russia with leading officials, he was told by General Yuri Baluyevsky, then the second highest-ranking officer in the Russian military, that LaRouche was the brains behind SDI. Rumsfeld stated that he believed LaRouche had had no influence whatsoever on the program, and surmised that Baluyevsky must have obtained the information off the Internet.[121] In 2012 the former head of the Russian bureau of Interpol, General Vladimir Ovchinsky, also described LaRouche as the man who proposed the SDI.[122]

1984: NBC lawsuit

In January 1984 NBC (National Broadcasting Company) aired a news segment about LaRouche, and in March a "First Camera" report produced by Pat Lynch. In an article for the *Columbia Journalism Review* in 1985, Lynch wrote that the reports included the allegation that LaRouche was "the leader of a violence-prone, anti-Semitic cult that smeared its opponents and sued its critics."[123] In interviews, former members of the movement gave details about their fundraising practices, and alleged that LaRouche had spoken about assassinating U.S. President Jimmy Carter. The reports said an investigation by the Internal Revenue Service (IRS) would lead to an indictment, and quoted Irwin Suall, the Anti-Defamation League's (ADL) fact-finding director, who called LaRouche a "small-time Hitler." After the broadcast, LaRouche members picketed NBC's office carrying signs saying "Lynch Pat Lynch," and the NBC switchboard said it received a death threat against her. Another NBC researcher said someone placed fliers around her parents' neighborhood saying she

was running a call-girl ring from her parents' home.[124] Lynch said LaRouche members began to impersonate her and her researchers in telephone calls, and called her "Fat Lynch" in their publications.[123]

LaRouche filed a defamation suit against NBC and the ADL, arguing that the programs were the result of a deliberate campaign of defamation against him.[125] The judge ruled that NBC need not reveal its sources, and LaRouche lost the case. NBC won a countersuit, the jury awarding the network $3 million in damages, later reduced to $258,459, for misuse of libel law, in what was called one of the more celebrated countersuits by a libel defendant.[126] LaRouche failed to pay the damages, pleading poverty, which the judge described as "completely lacking in credibility."[127] LaRouche said he had been unaware since 1973 who paid the rent on the estate, or for his food, lodging, clothing, transportation, bodyguards, and lawyers. The judge fined him for failing to answer. After the judge signed an order to allow discovery of LaRouche's personal finances, a cashier's check was delivered to the court to end the case.[128] When LaRouche appealed, the Fourth Circuit Court of Appeals, rejecting his arguments, set forth a three-pronged test, later called the "LaRouche test," to decide when anonymous sources must be named in libel cases.[129]

1985–1986: PANIC, LaRouche's AIDS initiative

Main article: 1986 California Proposition 64

LaRouche interpreted the AIDS pandemic as fulfillment of his 1973 prediction that an epidemic would strike humanity in the 1980s. According to Christopher Toumey, his subsequent campaign followed a familiar LaRouche pattern: challenging the scientific competence of government experts, and arguing that LaRouche had special scientific insights, and his own scientific associates were more competent than government scientists. LaRouche's view of AIDS agreed with orthodox medicine in that HIV caused AIDS, but differed from it in arguing that HIV spread like the cold virus or malaria, by way of casual contact and insect bites—which, if true, would make HIV-positive people extremely dangerous. He advocated testing anyone working in schools, restaurants, or healthcare, and quarantining those who tested positive. Some of LaRouche's views on AIDS were developed by John Seale, a British venereological physician who proposed that AIDS was created in a Soviet laboratory. Seale's highly speculative writings were published in three prestigious medical journals, lending these ideas some appearance of being hard science.[56]

LaRouche and his associates devised a "Biological Strategic Defense Initiative" that would cost $100 billion per annum, which they said would have to be directed by LaRouche. Toumey writes that those opposing the program, such as the World Health Organization and Centers for Disease Control, were accused of "viciously lying to the world," and of following an agenda of genocide and euthanasia.[130] In 1986 LaRouche proposed that AIDS be added to California's List of Communicable Diseases. Sponsored by his "Prevent AIDS Now Initiative Committee" (PANIC), Proposition 64—or the "LaRouche initiative"—qualified for the California ballot in 1986, with the required signature gatherers mostly paid for by LaRouche's Campaigner Publications. Seale, presented as an AIDS expert by PANIC, supported the LaRouche initiative, but disagreed with several of LaRouche's views, including that HIV could be spread by insects, and described the group's political beliefs and conspiracy theories as "rather odd".[131] According to David Kirp, professor of public policy at the University of California at Berkeley, the proposal would have required that 300,000 people in the area with HIV or AIDS be reported to public health authorities; might have removed over 100,000 of them from their jobs in schools, restaurants and agriculture; and would have forced 47,000 children to stay away from school.[132]

The proposal was opposed by leading scientists and local health officials as based on inaccurate scientific information and, as the public health schools put it, running "counter to all public health principles." It was defeated, reintroduced two years later, and defeated again, with two million votes in favor the first time, and 1.7 million the second. AIDS became a leading plank in LaRouche's platform during his 1988 presidential campaign.[133]

1986: Electoral success in Illinois; press conference allegations

In March 1986, Mark Fairchild and Janice Hart—LaRouche National Democratic Policy Committee candidates—won the Democratic primary for statewide offices in Illinois, bringing LaRouche national attention.[134] The Democratic gubernatorial candidate, Adlai Stevenson III, withdrew his nomination rather than run on the same slate as LaRouche members, and told reporters the party was "exploring every legal remedy to purge these bizarre and dangerous extremists from the Democratic ticket." A spokesman for the Democratic National Committee said it would have to do a better job of communicating to the electorate that LaRouche's National Democratic Policy Committee was unrelated to the Democratic Party.[135] *The New York Times* wrote that Democratic Party officials were trying to identify LaRouche candidates in order to alert voters, and asked the LaRouche organization to release a full list of its candidates.[136]

A month later, LaRouche held a press conference to accuse the Soviet government, British government, drug dealers, international bankers, and journalists of being involved in a variety of conspiracies. Flanked by bodyguards, he said, "If Abe Lincoln were alive, he'd probably be standing up here with me today," and that there was no criticism of him that did not originate "with the drug lobby or the Soviet operation ..." He said he had been in danger from Soviet assassins for over 13 years, and had to live in safe houses. He refused to answer a question from an NBC reporter, saying "How can I talk with a drug pusher like you?" He called the leadership of the United States "idiotic" and "berserk," and its foreign policy "criminal or insane." He warned of the imminent collapse of the banking system and accused banks of laundering drug money. Asked about the movement's finances, he said "I don't know. ... I'm not responsible, I'm not involved in that."[137]

1986–1988: Raids and criminal convictions

Main article: LaRouche criminal trials

In October 1986, hundreds of state and federal officers raided LaRouche offices in Virginia and Massachusetts. A federal grand jury indicted LaRouche and twelve of his associates on credit card fraud and obstruction of justice. The charges stated that they had attempted to defraud people of millions of dollars, including several elderly people, by borrowing money they did not intend to repay. LaRouche disputed the charges, alleging that they were politically motivated.[138]

When LaRouche's "heavily fortified"[139] estate was surrounded, he at first warned law-enforcement officials not to arrest him, saying that any attempt to do so would be an attempt to kill him. A spokesman would not rule out the use of violence against officials in response. While surrounded, LaRouche sent a telegram to President Ronald Reagan saying that an attempt to arrest him "would be an attempt to kill me. I will not submit passively to such an arrest, ... I will defend myself."[140][141]

In 1987, a number of LaRouche entities, including the Fusion Energy Foundation, were taken over through an involuntary bankruptcy proceeding. The government's use of a sealed order in this proceeding was regarded as a rare legal maneuver.[142]

On December 16, 1988, LaRouche was convicted of conspiracy to commit mail fraud involving more than $30 million in defaulted loans; eleven counts of actual mail fraud involving $294,000 in defaulted loans; and a single count of conspiring to defraud the U.S. Internal Revenue Service. He was sentenced to

15 years in federal prison, but was released on parole after serving five years on January 26, 1994.

Thirteen associates were sentenced to prison terms ranging from one month to 77 years for mail fraud and conspiracy.[138]

The trial judge called LaRouche's claim of a political vendetta "arrant nonsense", and said "the idea that this organization is a sufficient threat to anything that would warrant the government bringing a prosecution to silence them just defies human experience."[143]

Defense lawyers filed unsuccessful appeals that challenged the conduct of the grand jury, the contempt fines, the execution of the search warrants, and various trial procedures. At least ten appeals were heard by the United States Court of Appeals, and three were heard by the U.S. Supreme Court.

Former Attorney General Ramsey Clark joined the defense team for two appeals, writing that the case involved "a broader range of deliberate and systematic misconduct and abuse of power over a longer period of time in an effort to destroy a political movement and leader, than any other federal prosecution in my time or to my knowledge."[144]

In his 1988 autobiography, LaRouche says the raid on his operation was the work of Raisa Gorbachev.[145] In an interview that same year, he said that the Soviet Union opposed him, because he had invented the Strategic Defense Initiative. "The Soviet government hated me for it. Gorbachev also hated my guts and called for my assassination and imprisonment and so forth." He asserted that he had survived these threats, because he had been protected by unnamed U.S. government officials. "Even when they don't like me, they consider me a national asset, and they don't like to have their national assets killed."[146]

LaRouche received 25,562 votes in the 1988 presidential election.[147]

1989: Musical interests and Verdi tuning initiative

LaRouche had an interest in classical music up to the period of Brahms. A motto of LaRouche's European Workers' Party, is "Think like Beethoven"; movement offices typically include a piano and posters of German composers, and members are known for their choral singing at protest events and for using satirical lyrics tailored to their targets.[148] LaRouche abhorred popular music; he said in 1980, "Rock was not an accidental thing. This was done by people who set out in a deliberate way to subvert the United States. It was done by British intelligence", and wrote that the Beatles were "a product shaped according to British Psychological Warfare Division specifications."[149]

LaRouche movement members have protested at performances of Richard Wagner's operas, denouncing Wagner as an anti-Semite who found favor with the Nazis, and called a conductor "satanic", because he played contemporary music.[150]

In 1989 LaRouche advocated that classical orchestras should use a concert pitch based on A above middle C (A_4) tuned to 432 Hz, which the Schiller Institute called the "Verdi pitch", a pitch that Verdi had suggested as optimal, though he also composed and conducted in other pitches such as the French official *diapason normal* of 435 Hz, including his *Requiem* in 1874.[151]

The Schiller Institute initiative attracted support from more than 300 opera stars, including Joan Sutherland, Plácido Domingo, and Luciano Pavarotti, who according to *Opera Fanatic* may or may not have been aware of LaRouche's politics. A spokesman for Domingo said Domingo had simply signed a questionnaire, had not been aware of its origins, and would not agree with LaRouche's politics. Renata Tebaldi and Piero Cappuccilli, who were running for the European Parliament on LaRouche's "Patriots for Italy" platform, attended Schiller Institute conferences as featured speakers. The discussions led to debates in the Italian parliament about reinstating "Verdi" legislation. LaRouche gave an interview to National Public Radio on the initiative from prison. The initiative was opposed by the editor of *Opera Fanatic*, Stefan Zucker, who objected to the establishment of a "pitch police," and argued that LaRouche was using the issue to gain credibility.[152]

1990s

Imprisonment, release on parole, attempts at exoneration, visits to Russia

LaRouche began his jail sentence in 1989, serving it at the Federal Medical Center in Rochester, Minnesota. From there he ran for Congress in 1990, seeking to represent the 10th District of Virginia, but he received less than one percent of the vote. He ran for President again in 1992 with James Bevelas his running mate, a civil rights activist who had represented the LaRouche movement in its pursuit of the Franklin child prostitution ring allegations. It was only the second-ever campaign for president from prison.[153] He received 26,334 votes, standing again as the "Economic Recovery" party.[154] For a time he shared a cell with televangelist Jim Bakker. Bakker later wrote of his astonishment at LaRouche's detailed knowledge of the Bible. According to Bakker, LaRouche received a daily intelligence report by mail, and at times had information about news events days before they happened. Bakker also wrote that LaRouche believed their cell was bugged. In Bakker's view, "to say LaRouche was a little paranoid would be like saying that the *Titanic* had a little leak."[155]

Viktor Kuzin, a member of the Moscow City Council and a founder of the Democratic Union in Russia,[156] travelled to Minnesota in 1993 to meet LaRouche in prison, and afterwards participated in international campaigns to exonerate LaRouche.[157] An advertisement calling for exoneration was published in several U.S. newspapers, signed by Kuzin, Civil Rights attorney J. L. Chestnut, former Ugandan President Godfrey Binaisa, and others.[158]Chestnut was interviewed in the *Tuscaloosa News* saying that when he met LaRouche, "I told him that he might as well be black and in Alabama."[159]

The exoneration campaigns garnered the support of a number of State Representatives and State Senators in the U.S., as well as a former justice of the Washington State Supreme Court.[160][161]

LaRouche was released on parole in January 1994, and returned to Loudoun County. *The Washington Post* wrote that he would be supervised by parole and probation officers until January 2004.[162] Also in 1994, his followers joined members of the Nation of Islam to condemn the Anti-Defamation Leaguefor its alleged crimes against African Americans, reportedly one of several such meetings since 1992.[163]

The then former U.S. Attorney General Ramsey Clark wrote a letter in 1995 to then-Attorney General Janet Reno in which he said that the case against LaRouche involved "a broader range of deliberate and systematic misconduct and abuse of power over a longer period of time in an effort to destroy a political movement and leader, than any other federal prosecution in my time or to my knowledge". He asserted that, "The government, ex parte, sought and received an order effectively closing the doors of these publishing businesses, all of which were involved in First Amendment activities, effectively preventing the further repayment of their debts." He called the convictions "a tragic miscarriage of justice which at this time can only be corrected by an objective review and courageous action by the Department of Justice".[164] The LaRouche movement organized two panels to review the cases: the Curtis Clark Commission,[165] and the Mann-Chestnut hearings.[166]

Beginning in 1994, LaRouche made numerous visits to Russia, participating in conferences of the Vernadsky State Geological Museum of the Russian Academy of Sciences (RAS), the RAS Institute of the Far East, and other places. He addressed seminars at the RAS Institute of Economics, the RAS Institute

of Oriental Studies. He spoke at hearings in the State Duma of the Russian Federation on measures to ensure the development of the Russian economy at the point of destabilization of the world financial system. Two of his books were translated into Russian.[167]

On September 18, 1996, a full-page advertisement appeared in the *New Federalist*, a LaRouche publication, as well as *The Washington Post* and *Roll Call*. Entitled "Officials Call for LaRouche's Exoneration", its signatories included Arturo Frondizi, former President of Argentina; figures from the 1960s American civil rights movement such as Amelia Boynton Robinson (a leader of the Larouche-affiliated Schiller Institute), James Bevel (a Larouche movement participant) and Rosa Parks; former Minnesota Senator and Democratic presidential candidate Eugene McCarthy; Mervyn Dymally, who chaired the Congressional Black Caucus; and artists such as classical vocalist William Warfield and violinist Norbert Brainin, former 1st Violin of the Amadeus Quartet.[168]

In 1996, LaRouche was invited to speak at a convention organized by the Nation of Islam's Louis Farrakhan and Ben Chavis, then of the National African American Leadership Summit. As soon as he began speaking, he was booed off the stage.[169]

In the 1996 Democratic Party presidential primaries, he received enough votes in Louisiana and Virginia to get one delegate from each state, but before the primaries began, the Democratic National Committee chair, Donald Fowler, ruled that LaRouche was not a "bona fide Democrat" because of his "expressed political beliefs ... which are explicitly racist and anti-Semitic," and because of his "past activities, including exploitation of and defrauding contributors and voters." Fowler instructed state parties to disregard votes for LaRouche.[170]

LaRouche opposed attempts to impeach President Bill Clinton, charging it was a plot by the British Intelligence to destabilize the U.S. Government.[171][172] In 1996 he called for the impeachment of Pennsylvania governor Tom Ridge.[173][174]

Efforts to clear LaRouche's name continued, including in Australia, where the Parliament acknowledged receipt of 1,606 petition signatures in 1998.[175]

In 1999 China's press agency, the Xinhua News Agency, reported that LaRouche had criticized the Cox Report, a congressional investigation that accused the Chinese of stealing U.S. nuclear weapons secrets, calling it a "scientifically illiterate hoax."[176] On October 13, 1999, during a press conference to announce his plans to run for president, he predicted the collapse of the world's financial system, stating, "There's nothing like it in this century. ... it is systematic, and therefore, inevitable." He said the U.S. and other nations had built the "biggest financial bubble in all history," which was close to bankruptcy.[177]

2000s

2000–2003: Worldwide LaRouche Youth Movement, September 11 Attacks, presidential run

LaRouche supporters in Chicago, 2007

LaRouche founded the Worldwide LaRouche Youth Movement (WLYM) in 2000, saying in 2004 that it had hundreds of members in the U.S. and a lesser number overseas. During the Democratic primaries in June 2000, he received 53,280 votes, or 22 percent of the total, in Arkansas.[178]

In 2002 LaRouche's *Executive Intelligence Review* argued that the September 11, 2001 attacks had been an "inside job"and "attempted coup d'etat", and that Iran was the first country to question it. The article received wide coverage in Iran, and was cited by senior Iranian government officials, including Akbar Hashemi Rafsanjani and Hassan Rouhani. Mahmoud Alinejad wrote that, in a subsequent telephone interview with the *Voice of the Islamic Republic of Iran*, LaRouche said the attacks had been organized by rogue elements inside the U.S., aiming to use the incident to promote a war against Islam, and that Israel was a dictatorial regime prepared to commit Nazi-style crimes against the Palestinians.[179]

In 2003 LaRouche was living in a "heavily guarded" rented house in Round Hill, Loudoun County, Virginia.[180]

LaRouche again entered the primary elections for the Democratic Party's nomination in 2004, setting a record for the number of consecutive presidential campaigns; Democratic Party officials distanced themselves from him and did not allow him to participate in candidate forum debates. He did not run in 2008.[181]

As during the preceding decade, LaRouche and his followers denied that human civilization had harmed the environment through DDT, chlorofluorocarbons, or carbon dioxide. According to Chip Berlet, "Pro-LaRouche publications have been at the forefront of denying the reality of global warming".[182]

2003–2012: Overseas press coverage, financial crisis

Iqbal Qazwini wrote in the Arabic-language daily *Asharq Al-Awsat* in 2003 that LaRouche was one of the first to predict the fall of the Berlin Wall in 1988 and German unification. He said LaRouche had urged the West to pursue a policy of economic cooperation similar to the Marshall Plan for the advancement of the economy of the socialist countries. According to Qazwini, recent years have seen a proliferation of LaRouche's ideas in China and South Asia. Qazwini referred to him as the spiritual father of the revival of the new Silk Road or Eurasian Landbridge, which aims to link the continents through a network of ground transportation.[183]

In April 2005, Tang Yong of the *People's Daily* of China covered LaRouche's record of economic forecasting, and his warning that the present financial and currency system was already unsalvageable, thus it must be radically restructured, not just merely reformed.[184] Later that year, the paper published an eight-part interview with LaRouche, covering his economic forecasts, his battles with the American media, and his assessment of the neoconservatives. The interviewer wrote that LaRouche was "quite famous in mainland China today," and seemed to be better known overseas than in America.[185]

In 2007, LaRouche began a national lobbying campaign to restore the Glass-Steagall Act, saying that it would be possible to save the U.S. banking system by reorganizing it under bankruptcy protection.[186] Also during 2007 he proposed a "Homeowners and Bank Protection Act". This called for the establishment of a federal agency that would "place federal- and state-chartered banks under protection, freeze all existing home mortgages for a period of time, adjust mortgage values to fair prices, restructure existing mortgages at appropriate interest rates, and write off speculative debt obligations of mortgage-backed securities". The bill envisioned a foreclosure moratorium, allowing homeowners to make the equivalent of rental payments for an interim period, and an end to bank bail-outs, forcing banks to reorganize under bankruptcy laws.[187]

In Spring 2007 he was an honorary foreign guest at a ceremony in honor of the 80th birthday of Stanislav Menshikov at the Russian Academy of Sciences.[167]

2009: U.S. health care reform

LaRouche poster of Barack Obama with a 'Hitler mustache'

During the discussion of U.S. health care reform in 2009, LaRouche advocated a single-payer health care bill and took exception to what he described as

During the discussion of U.S. health care reform in 2009, LaRouche advocated a single-payer health care bill and took exception to what he described as Barack Obama's proposal that "independent boards of doctors and health care experts [should] make the life-and-death decisions of what care to provide, and what not, based on cost-effectiveness criteria." LaRouche said the proposed boards, later compared to "death panels" by Sarah Palin, would amount to the same thing as the Nazis' Action T4 euthanasia program, and urged Americans to "quickly and suddenly change the behavior of this president ... for no lesser reason than that your sister might not end up in somebody's gas oven."

Images at tables of volunteers compared Obama to Hitler, and at least one had a picture of Obama with a Hitler-style mustache. In Seattle, police were called twice in response to people threatening to attack the volunteers. During one widely reported public meeting, Congressman Barney Frank referred to the images as "vile, contemptible nonsense."[188][189][190][191][192][193][194]

Ideology and beliefs

Main article: Views of Lyndon LaRouche and the LaRouche movement

History as a struggle between Platonism and Aristotelianism

University of Notre Dame political philosophers Catherine Zuckert and Michael Zuckert write about LaRouche that "[I]t must be nearly unique in American politics that a presidential candidate ... makes the interpretation of Plato a major issue in his campaign."[195]

According to George Johnson, LaRouche saw history as a battle between Platonists, who believe in absolute truth, and Aristotelians, who rely on empirical data. Johnson characterizes LaRouche's views as follows: the Platonists include figures such as Beethoven, Mozart, Shakespeare, Leonardo da Vinci, and Leibniz. LaRouche believed that many of the world's ills result from the dominance of Aristotelianism as embraced by the empirical philosophers(such as Hobbes, Locke, Berkeley, and Hume), leading to a culture that favors the empirical over the metaphysical, embraces moral relativism, and seeks to keep the general population uninformed. Industry, technology, and classical music should be used to enlighten the world, LaRouche argued, whereas the Aristotelians use psychotherapy, drugs, rock music, jazz, environmentalism, and quantum theory to bring about a new Dark Age in which the world will be ruled by the oligarchs. Left and right are false distinctions for LaRouche; what matters is the Platonic versus Aristotelian outlook, a position that has led him to form relationships with groups as disparate as farmers, nuclear engineers, Black Muslims, Teamsters, and pro-life advocates.

In *Architects of Fear* (1983), Johnson compares LaRouche's view to an Illuminati conspiracy theory; Johnson writes that after he wrote about LaRouche in *The Minneapolis Star*, LaRouche's followers denounced him as part of a conspiracy of elitists that began in ancient Egypt.[196][197][198][199][200] However, according to LaRouche, Aristotelians are not necessarily in communication or coordination with one another: "From their standpoint, [they] are proceeding by instinct," LaRouche said. "If you're asking how their policy is developed—if there is an inside group sitting down and making plans—no, it doesn't work that way ... History doesn't function quite that consciously."[201][196][202][203][204]

Controversy

Despite LaRouche's self-identification with the left and some left-wing policies, his critics have said that he had "fascistic tendencies", took positions on the far right, and created disinformation.[205]

Designation as conspiracy theorist

LaRouche was commonly regarded as a conspiracy theorist, for example by his Fox News obituary.[206] An article in the Southern Poverty Law Center[207]website names him as "a fringe ideologue and conspiracy theorist whom Chip Berlet, senior analyst at Political Research Associates and an expert on the radical right calls “the man who brought us fascism wrapped in an American flag”." An NPR obituary is titled *Conspiracy Theorist And Frequent Presidential Candidate Lyndon LaRouche Dies At 96*[208]. *The Washington Post* obituary reports he was "often described as an extremist crank and fringe figure" and that he "built a worldwide following based on conspiracy theories, economic doom, anti-Semitism, homophobia and racism".[209]

Allegations of antisemitism

LaRouche and his ideas have been called antisemitic since at least the mid-1970s by dozens of individuals and organizations in countries across Europe and North America. LaRouche and his followers have responded to these allegations by claiming that LaRouche has Jewish supporters and denied the accusations.

Starting in the mid-1970s allegations appeared that LaRouche had fascist and antisemitic tendencies.[210]

In 1977 LaRouche married his second wife, Helga Zepp-LaRouche, a German 27 years younger than he. Her 1984 book, *The Hitler Book*, argues that "We need a movement that can finally free Germany from the control of the Versailles and Yalta treaties, thanks to which we have staggered from one catastrophe to another for an entire century."[211] Helga founded the Schiller Institute, which has been accused of antisemitism by the *Berliner Zeitung* and Political Research Associates, a non-profit research group which studies right wing, white supremacist, and militia groups.[212][213]

LaRouche claimed that he was anti-Zionist, not antisemitic.[214] When the Anti-Defamation League accused LaRouche of antisemitism in 1979, he filed a $26-million libel suit; however, the case failed when Justice Michael Dontzin of the New York Supreme Court ruled that it was fair comment and that the facts "reasonably give rise" to that description.[215][216] LaRouche started a campaign against the Anti-Defamation League of B'nai B'rith (ADL) and set up a group called "The Provisional Committee to Clean Up B'nai Brith."[*citation needed*] LaRouche said in 1986 that descriptions of him as a neo-fascist or anti-Semite stemmed from "the drug lobby or the Soviet operation—which is sometimes the same thing,"[217][218] and in 2006 wrote that "religious and racial hatred, such as antisemitism, or hatred against Islam, or, hatred of Christians, is, on record of known history, the most evil expression of criminality to be seen on the planet today."[219] Antony Lerman wrote in 1988 that LaRouche used "the British" as a code word for "Jews,"[220] a theory also propounded by Dennis King, author of *Lyndon LaRouche and the New American Fascism* (1989). George Johnson argued that King's presentation failed to take into account that several members of LaRouche's inner circle were themselves Jewish.[221] Daniel Pipes wrote in 1997 that LaRouche's references to the British really were to the British, though he agreed that an alleged British-Jewish alliance lay at the heart of LaRouche's conspiracism.[222] It was reported in 1989 that many members of LaRouche's inner circle were Jewish.[76]

As of 2016, the Jewish Virtual Library states that "The international organization run by Lyndon LaRouche is a major source of such masked antisemitic theories globally. In the U.S. the LaRouchites spread these conspiracy theories in an alliance with aides to Minister Louis Farrakhan of the Nation of Islam. A series of LaRouchite pamphlets calls the neoconservative movement the "Children of Satan", which links Jewish neo-conservatives to the historic rhetoric of the blood libel.[223]

the blood libel.[—]

Allegations of racism

Manning Marable of Columbia University wrote in 1998 that LaRouche tried in the mid-1980s to build bridges to the black community. Marable argued that most of the community was not fooled, and quoted the A. Philip Randolph Institute, an organization for African-American trade unionists, declaring that "LaRouche appeals to fear, hatred and ignorance. He seeks to exploit and exacerbate the anxieties and frustrations of Americans by offering an array of scapegoats and enemies: Jews, Zionists, international bankers, blacks, labor unions—much the way Hitler did in Germany."[224] During LaRouche's slander suit against NBC in 1984, Roy Innis, leader of the Congress of Racial Equality, took the stand for LaRouche as a character witness, stating under oath that LaRouche's views on racism were "consistent with his own." Asked whether he had seen any indication of racism in LaRouche's associates, he replied that he had not.[225]

Disputed record as economist and forecaster

LaRouche material frequently acclaims him as the world's greatest economist and the world's most successful forecaster. For example, his book title *The Economics of The Noösphere: Why Lyndon LaRouche Is The World's Most Successful Economic Forecaster Of the Past Four Decades*.[226]

However, a website of disgruntled ex-movement leaders lists incorrect predictions of sudden world economic collapse, war or depression in the years 1956, 1961-1970, 1972, 1975-1992,[227] and 1994-2011.[228]

Apart from the numerous failed predictions are claimed some successful predictions or proposals: the eventual reunification of Germany[228], the Star Wars initiative, the New Silk Road[228] (claimed as a precursor to the Chinese One Belt One Road initiative.)

Movement

Main article: LaRouche movement

Estimates of the size of LaRouche's movement have varied over the years; most say there is a core membership of 500 to 2,000. The estimated 600 members in 1978 paid monthly dues of $24. Johnson wrote in 1983 that both the Fusion Energy Foundation and the National Democratic Policy Committee had attracted some 20,000 members, as well as 300,000 magazine subscribers.[229][230][231][232][233][234]

According to Christopher Toumey, LaRouche's charismatic authority within the movement was grounded on members' belief that he possessed a unique level of insight and expertise. He identified an emotionally charged issue, conducted in-depth research into it, and then proposed a simplistic solution, which usually involved restructuring of the economy or national security apparatus. He and the membership portrayed anyone opposing him as immoral and part of the conspiracy.[235][236][237]

Characterization as a cult

The LaRouche movement, has been described as a cult or cult-like by critics and anti-cult organizations.[238][239][240][241][242]

A 1987 article by John Mintz in *The Washington Post* reported that members lived hand-to-mouth in crowded apartments, their basic needs, such as a mattress and pillowcase, paid for by the movement. They worked raising money or selling newspapers for LaRouche, doing research for him, or singing in a group choir, spending almost every waking hour together.[243]

The group is known for its caustic attacks on people it opposes and former members. In the past it has justified what it refers to as "psywar techniques" as necessary to shake people up; Johnson in 1983 quoted a LaRouche associate: "We're not very nice, so we're hated. Why be nice? It's a cruel world. We're in a war and the human race is up for grabs."[244] Charles Tate, a former long-term LaRouche associate, told *The Washington Post* in 1987 that members see themselves as not subject to the ordinary laws of society: "They feel that the continued existence of the human race is totally dependent on what they do in the organization, that nobody would be here without LaRouche. They feel justified in a peculiar way doing anything whatsoever."[243]

Death

LaRouche's death was announced on the website of one of his organizations. He died on February 12, 2019, at age 96. Neither the place nor cause of his death was specified.[1]

Alexander Duncan Langmuir (12 September 1910 – 22 November 1993) was an American epidemiologist. He is renowned for creating the Epidemic Intelligence Service.

Biography

This photograph depicts Dr. Alexander D. Langmuir seated beside Ms. Ida Sherwood during an Epidemic Intelligence Service (EIS) luncheon.

Alexander D. Langmuir was born in Santa Monica, California. He received his A.B. in 1931 from Harvard, his M.D. in 1935 from Cornell University Medical College, and his M.P.H. in 1940 from the Johns Hopkins School of Hygiene and Public Health. After serving as a public health officer in New York and as an epidemiologist with the U. S. Army from 1942 to 1946, Langmuir returned to Johns Hopkins to become associate professor of epidemiology in the school of medicine. In 1949, he became director of the epidemiology branch of the National Communicable Disease Center (now the Centers for Disease Control and Prevention) in Atlanta, a position he held for over 20 years. He wrote extensively on all phases of epidemiology on a global basis and was recognized internationally as a leading contributor in epidemiology. Langmuir was a visiting professor at the Johns Hopkins School of Hygiene and Public Health from 1988 until his death in 1993.

Date of Birth: September 12, 1910 [,] Santa Monica, California

Education:

- Harvard College, Cambridge, MA
  - Major: Physics, A.B. (cum laude)
  - 1927-1931
- Cornell University Medical College
  - Doctor of Medicine
  - 1931-1935
- Boston City Hospital
  - Internal Medicine
  - 1935-1937
- Johns Hopkins University School of Hygiene and Public Health
  - Masters in Public Health
  - 1940

Appointments:

- Medical Consultant, pneumonia control, New York State Health Department, Albany, NY
- 1937-1939
- Assistant District Health Officer, New York State Institute of Health, Albany, NY
- 1940-1941
- Deputy Commissioner of Health, Westchester County Health Department, Peekskill, NY
- 1941-1942
- Epidemiologist, Commission on Acute Respiratory Diseases, Army Epidemiological Board, Fort Bragg, NC
- 1942-1946
- Associate Professor of Epidemiology, Johns Hopkins University School of Hygiene and Public Health, Baltimore, MD
- 1946-1949
- Chief Epidemiologist, Communicable Disease Center (now known as the Centers for Disease Control and Prevention), Atlanta, GA
- 1949-1970
- Clinical Professor of Preventive Medicine and Community Health, Emory University, Atlanta, GA
- 1950-1970
- Visiting Professor of Epidemiology, Harvard Medical School, Boston, MA
- 1970-1977
- Retired, lived in Chilmark, Martha's Vineyard Island, MA
- 1977-1992
- Visiting Professor of Epidemiology, Johns Hopkins University School of Hygiene and Public Health, Baltimore, MD
- 1988-1993

Abstract - This article considers the imbrication of war-time logics with the ideational and institutional development of public health surveillance. It suggests that, as the Cold-War–era gave way to the 'age of globalization', public health discourse became less concerned with ideological enemies, and more concerned with ontological enemies. The discourse of emerging infectious disease exemplifies this preoccupation and illustrates how public health surveillance, dominated by war-time logics, is both globalized and predisposed to marginalized local orders of concern. However, at the same time that militarized configurations of public health surveillance set certain tendencies in motion, local orders of concern deconstruct, contest, resist, and negotiate these tendencies. Hence, this article concludes with a call for further empirical attention by Surveillance Studies scholars to the multiplicity of local sites that enact public health surveillance.

Introduction

In 1951 the United States (US) Department of Defense and the US Federal Civil Defense Administration aired a television program entitled What You Should Know About Biological Warfare. The program featured Alexander Langmuir, a decisive figure, as it turns out, in the history of public health. In the program, Langmuir presented a scary picture of the precise ways in which biological weapons could be deployed in attacks against the United States. He also made the case for a public health system that could defend against this threat. Elizabeth Fee and Theodore Brown give the following description:

At one point in the program, Langmuir turned on a Waring blender filled with dry ice for a vivid demonstration of how clouds of aerosol mist could contaminate a whole studio and infect everyone inside. He then used a familiar can of insecticide to demonstrate the working of an aerosol spray. Employing much the same principles, he said, an enemy could mount aerosols on airplanes and cover a city with a vast cloud of infectious material. Langmuir also injected colored liquid into a model of the water supply of a city to show how easily a biological warfare agent could spread. How could anyone protect or defend against such an attack? [...] In short, he said, the country needed an epidemic intelligence service (2001: 722-723).

Langmuir was able to successfully capitalize on fear about biological warfare by capturing the political will and funding for one of the most comprehensive public health surveillance undertakings in the world.

His creation of a highly trained cadre of disease detectives, and the institutional apparatus to support them, stands out amongst the achievements in the history of American public health. To some, Langmuir's use of the biological warfare issue to build public health infrastructure amounted to making

Alex Langmuir was born in Santa Monica, California, and grew up in New Jersey. His uncle, Irving Langmuir, a physicist and chemist, won the Nobel Prize in Chemistry in 1932. At Harvard College, Alex Langmuir tried to follow in his uncle's footsteps, but he found that the mathematics of advanced physics was beyond him and thus decided to pursue a career in medicine. He received his AB (cum laude) in 1931 from Harvard and his MD in 1935 from Cornell University Medical College. As a college student, Langmuir was inspired by Massachusetts Commissioner of Health George Hoyt Bigelow to enter the field of public health. His first 2 jobs were with the New York State Health Department; he began as a medical consultant and then became an assistant district health officer in Albany. After graduating with an MPH from the Johns Hopkins School of Hygiene and Public Health in 1940, Langmuir became a deputy commissioner of health in Westchester County, New York. His family was dismayed that he chose a career in public health rather than clinical medicine, but Langmuir expressed in his later years that his time in local public health taught him lessons that were fundamental to his achievements. From 1942 to 1946, he served as an epidemiologist with the Armed Forces Epidemiologic Board's Commission on Acute Respiratory Diseases, stimulating his lifelong interest in influenza. In 1946, Langmuir returned to Johns Hopkins University as an associate professor of epidemiology. However, by 1949 he was restive in academia and was attracted to the challenge of becoming the first chief epidemiologist of the newly established Communicable Disease Center (now the Centers for Disease Control and Prevention [CDC]) in Atlanta, Georgia, a position he held for over 20 years. When Langmuir retired from CDC, he became a visiting professor of epidemiology at Harvard Medical School and, later, a visiting professor of epidemiology at Johns Hopkins School of Hygiene and Public Health. He wrote extensively on all phases of epidemiology and public health surveillance on a global basis and was recognized internationally as an assertive public health authority.

[Consider this - One Health and CDC are this historically connected to biowarfare]

In 1951, following the start of the Korean War, Langmuir established the EIS program as an early warning system against biologic warfare. EIS officers then and now are physicians, veterinarians, nurses, and health scientists who serve 2-year assignments. In an obituary written for the New York Times, Lawrence Altman said Langmuir "taught what he called 'shoe leather epidemiology,' stressing that investigators go into the field to collect their own data and view directly the locale of the public health problem they were investigating." Langmuir said: "Each epidemic aid call was an adventure and a training experience, even the false alarms." He stressed that field epidemiology should be taught in the field, not in the classroom. Admission into the EIS program was highly selective. Langmuir believed that when competent persons were thrust into challenging circumstances with supportive supervision, excellent results were certain. He regarded the EIS officers as members of his extended family, backing them firmly when they found themselves in difficulty and joining them for the roasts of CDC leaders during the officers' annual skit night—often at his own expense.

In 1955, Langmuir and his young staff achieved early recognition due to the "Cutter Incident." The new inactivated (Salk) polio vaccine was causing cases of polio. Surgeon General Leonard Scheele asked Langmuir to develop a surveillance system to determine the extent of the problem. Langmuir deployed his staff, and within days they determined that the cases were caused by vaccine from a single manufacturer: Cutter Laboratories. "Langmuir was able to predict with great accuracy the expected size of the epidemic and the number of secondary cases that would occur," former CDC director William Foege noted. This response enhanced the reputation of the young agency and established epidemic aid as one of its singular characteristics.

Today, the EIS program has evolved into a surveillance and response unit for all types of health problems. During 1951–2014, more than 3,500 physicians, veterinarians, nurses, and health scientists were trained as EIS officers. Many of the nation's medical and public health leaders, including CDC directors, state health department directors, state epidemiologists, and deans of the country's premier schools of public health, are EIS alumni. Since 1980, CDC has supported the development and implementation of 48 two-year field epidemiology training programs that cover 60 countries and are modeled after the EIS in their teaching and practice of applied field epidemiology. More than 3,000 epidemiologists have graduated from these programs; many of these graduates now hold leadership positions within their countries' ministries of health, the World Health Organization, and other global health organizations.

The idea of effective national disease surveillance captured Alex Langmuir's imagination throughout his career. He believed that surveillance is the foundation for evidence-based public health action. Langmuir preached the importance of the systematic collection of pertinent data, the consolidation and analysis of these data into useful information, and the dissemination of the results to all who need to know so that they can take action. His goal was to use surveillance systems to define populations at risk for disease, determine interventions, and monitor their impact. Langmuir and his staff developed novel national surveillance programs for an array of communicable diseases and for chronic diseases, injuries, and reproductive health. Indeed, he considered the population explosion to be the most serious epidemic of all.

Altman described Langmuir as "a tall man who could command immediate attention when he stood to speak to audiences in his deep voice. He thrived on controversy and took pride in overcoming local political pressures to crusade for preventive medicine and other measures to safeguard public health." Philip Brachman, who succeeded Langmuir as EIS director, described Langmuir as "visionary, clairvoyant, tenacious, well prepared, scientifically honest, and optimistic." Langmuir enjoyed being a civil servant and working to benefit the public. "His concerns were to control and prevent disease by applying the principles of epidemiology to the identification of causes and solutions," Brachman wrote. Foege described Langmuir as someone with a public health message who arrived at the right time and place in history to be able to broadly disseminate his message.

In 1979, when Alex Langmuir was interviewed by D.A. Henderson about being recruited to work at CDC in 1949, Langmuir said, "As I looked it over and saw the vision, there was no question, [former CDC director] Justin Andrews took me to the mountain and showed me the Promised Land." At CDC, Alex Langmuir changed the way epidemiology is used in public health practice, first in the United States and then throughout the world. In the 65 years since Langmuir's arrival at CDC, his disciples—EIS and field epidemiology training program officers—have played pivotal roles in combating the root causes of major public health problems. Millions of persons live longer and healthier lives because of the accomplishments of Langmuir and his progeny in controlling and preventing disease. This is Alex Langmuir's grand legacy.

By Lawrence K. Altman

- Nov. 24, 1993

Dr. Alexander D. Langmuir, a leader in public health who is credited with saving hundreds of thousands of lives through his innovations in controlling epidemics, died on Monday in Baltimore, where he lived. He was 83.

The cause was kidney cancer, the Department of Health and Human Services said.

In 1949, Dr. Langmuir created a corps of epidemiologists at what is now the Federal Centers for Disease Control and Prevention in Atlanta. The corps was ready to fly anywhere immediately to investigate reports of an epidemic or an unusual cluster of cases. Known as the Epidemic Intelligence Service, the program played a crucial role in turning what was then an obscure and fledgling operation into a large Federal agency.

From 1949 to 1970, Dr. Langmuir was the disease centers' chief epidemiologist. When he retired, he taught at Harvard Medical School, staying until 1977.

Trained 500 Health Workers

As the Government's chief disease detective, he created the concept of surveillance for infectious diseases. The agency uses it to track dozens of diseases and to analyze patterns to take steps to prevent clusters and outbreaks from becoming epidemics. The agency also responds to requests from state health departments to investigate unusual cases and clusters.

It is through such investigations that scientists at the disease centers discovered the bacterium that causes Legionnaire's disease, identified toxic shock syndrome, and last week reported isolating and growing the strain of Hantavirus that causes a fatal illness first reported among Navajo Indians in New Mexico this year.

Dr. Langmuir trained the first 500 of the more than 2,200 doctors, veterinarians, statisticians and other health workers who have graduated from the epidemic intelligence program. Many now teach and conduct research in the country's schools of medicine and public health, and many others work in health departments throughout the country. Some have gone on to establish similar programs in other countries.

But when **Dr. Langmuir formed the Epidemic Intelligence Service,** he said the Atlanta agency's activity was limited primarily to malaria. It was "a bouncing, thriving, adolescent, gawky and awkward organization," he said.

"The information about malaria in the country was abominable," he recalled when he left the disease centers in 1970. Texas was reporting 10,000 cases a year, other states, 5,000. "It was perfectly clear there was gross error in the reporting," Dr. Langmuir said, adding that he was upset that the centers did not challenge the diagnosis of the doctors and state health officials.

Relished Jurisdictional Fights

Dr. Langmuir was a tall man who could command immediate attention when he stood to speak to audiences in his deep voice. He thrived on controversy and often took pride in overcoming local political pressures to crusade for preventive medicine and other measures to safeguard public health.

He relished jurisdictional and other fights with state and Federal officials and other scientists, including some on his own staff. In creating the E.I.S., Dr. Langmuir said he and officials of the National Institutes of Health "almost went to fisticuffs" as he overcame their opposition.

Dr. Langmuir taught what he called "shoe leather epidemiology," stressing that investigators go into the field to collect their own data and view directly the locale of the public health problem they were investigating. His graduates wore lapel pins of a shoe with a hole in the sole.

He paid careful attention to studying the way infectious and communicable agents spread -- through the air, water and food. Dr. Langmuir attributed his success to good communications with other scientists and health officials. He required investigators to write reports immediately and to send copies to all who needed the information.

Under his leadership, epidemiologists at the disease centers traced a number of cases of paralytic polio to the defective manufacture of a polio vaccine by Cutter Laboratories.

When the possibility of biological warfare was raised during the Korean War, scientists looked to epidemiology as the first line of defense. But the country was not prepared. Dr. Langmuir seized the opportunity to strengthen disease surveillance and his program. He found many young doctors facing the draft willing to spend two years learning epidemiology in the Public Health Service to fulfill their military service.

In later years, Dr. Langmuir criticized the disease centers for what he said was the poor quality of its epidemiological investigations of AIDS.

Grew Up in New Jersey

Alexander Duncan Langmuir was born on Sept. 22, 1910, in Santa Monica, Calif., and grew up in New Jersey.

At Harvard College, his studies were influenced by his uncle, Irving Langmuir, a physicist and chemist who won the Nobel Prize in Chemistry in 1932. But Alexander Langmuir said he found the advanced mathematics of physics "just impossible." So he went to medical school, receiving a degree from Cornell and interning at the Boston City Hospital. His math training and a flair for statistics helped him earn a degree in public health from Johns Hopkins University in Baltimore.

He then worked for the New York State Health Department in Albany and as Deputy Commissioner of Health for Westchester County. In World War II he was a member of the Army's Commission on Acute Respiratory Diseases at Fort Bragg, N.C.

After the war he returned to Johns Hopkins. But he left for the disease centers because, he later said, he "was rather disenchanted with academic life at Johns Hopkins."

In 1988, he returned to Johns Hopkins where, earlier this year, students selected him as an outstanding teacher.

Among his awards were those from the Charles A. Dana Foundation for pioneering achievements in public health, the American Public Health Association and the Royal Society of Medicine in England. He was a member of the Institute of Medicine of the National Academy of Sciences, a Fellow of the American Academy of Arts and Sciences, and a number of other professional organizations.

Dr. Langmuir married twice. His first wife was the former Sara Ann Harper. His second was Dr. Leona Baumgartner, a former Commissioner of Health in New York City. Both have died.

He is survived by three daughters, Anne Ruggles of Atlanta, Susan Davis of Philadelphia and Lynn Adams of Boston; a son, Paul H., of Providence, R.I.; a brother, David, of Los Angeles; a sister, Edith Leverenz of Naples, Fla., five grandchildren and three great-grandchildren.

Who is Alexander Langmuir?

By Vincent Iannelli, MD / August 15, 2018 / Alexander Langmuir, epidemiology, GBS, Guillain-Barré Syndrome, measles, polio, swine flu, The Cutter Incident

Alexander Langmuir is typically described as a hero or titan of public health.

Then why do some folks think he was against the flu and measles vaccines?

Who is Alexander Langmuir?

Dr. Alexander Langmuir has been called the father of infectious disease epidemiology.

Why?

In 1949, he established the CDC's Epidemiology Program. Actually, at the time, the CDC was still called the Communicable Disease Center.

Dr. Alexander Langmuir and his Polio Surveillance Unit at the EIS in 1955.

Dr. Alexander Langmuir and his Polio Surveillance Unit at the EIS in 1955.

Dr. Langmuir, as Chief Epidemiologist at CDC for 21 years, also:

founded the Epidemic Intelligence Service (EIS)

instituted a malaria surveillance system

established national disease surveillance system for the United States

was involved in resolving the Cutter incident

brought the Morbidity and Mortality Weekly Report to CDC

investigated the swine influenza virus vaccine incident, when it was thought that some people developed GBS after getting the new swine flu vaccine in 1976

His work saved the lives of hundreds of thousands of people.

Don't believe any propaganda or quotes without sources attributed to Alexander Langmuir.

Don't believe any propaganda or quotes without sources attributed to Dr. Alexander Langmuir.

Did he ever tell folks to not get a flu shot?

Was he ever concerned about mercury in flu shots?

Considering that Dr. Langmuir died in 1993, before folks became concerned about thimerosal in vaccines, that's unlikely. That's especially so considering that the only place you can find these types of quotes are on anti-vaccine websites.

Still, Langmuir was critical of flu shots.

Dr. Marcelle C. Layton (born 1958)

2004 Interview with Marcelle C. Layton, MD : "BIOSECURITY AND BIOTERRORISM: BIODEFENSE STRATEGY, PRACTICE, AND SCIENCE, Volume 2, Number 4, 2004"

Interview with Marcelle C. Layton, MD : Assistant Commissioner, Bureau of Communicable Disease, New York City Department of Health and Mental Hygiene

Source : [HP006E][GDrive]

In 1992, Marci Layton, an infectious disease fellow at Yale University, applied for an Epidemic Intelligence Service (EIS) position with the U.S. Centers for Disease Control and Prevention (CDC). "When I was trying to decide where I wanted to do my two-year fellowship, I happened to bump into the current EIS officer in New York City. He said that if I really enjoyed infectious diseases and didn't want to specialize in just one, instead of traveling abroad—which reportedly gets old after a while—I could come to New York and work on a variety of things with the advantage of still sleeping in my own bed at night."

Layton was dubious. "I couldn't imagine living in New York City. It wasn't my first choice for EIS—it was my third choice. The city intimidated me. I'm by nature quiet, and not a public person. I originally wanted to be in New England or someplace more rural." Nevertheless, New York City is where she landed—just as a series of unprecedented infectious disease outbreaks was about to strike. In August 1994, she formally joined the department as Assistant Commissioner of Communicable Disease. Today, the EIS officer who had originally talked up New York City— Thomas Frieden, MD, MPH—is her Commissioner.

After ten years, more than a thousand outbreak investigations, a tuberculosis epidemic, the hemispheric debut of West Nile virus, the September 11 attacks, anthrax spores in the mail, the global SARS threat, a massive bioterrorism preparedness campaign, and countless other crises, Layton has more than adapted to the job. Her cool head, ferocious work ethic, and visionary approach to surveillance and communications have won her international respect.

After the 2001 terrorist attacks, Layton received numerous professional awards—honors that she insists belong to her entire department. "But the one that meant a lot to me was from the Council of State and Territorial Epidemiologists, the Pumphandle Award." It was given, in part, for her department's swift and fact-filled updates during the World Trade Center attacks and the city's anthrax outbreak that were shared with other state and local health departments nationwide. "I used to say, when I got awards like that, 'Wait a minute, you're supposed to get these at the end of your career.'"

Only in her mid-40s, Layton acknowledges that she has already entered the annals of public health history—an area of scholarship that itself fascinates her. "My dream retirement job is getting a degree in the history of medicine and specializing in the history of public health in New York City. I give a lot of talks. If I had to talk about hypertension or diabetes management, I wouldn't be able to give 30 talks a year—I would fall asleep while I was talking. But once I start talking about

something we've been through here—whether it's West Nile or anthrax or SARS—I get completely engaged. I happened to stumble into something that fits me perfectly."

Layton spoke on November 6, 2004, with Madeline Drexler, a Boston-based journalist and author of Secret Agents: The Menace of Emerging Infections

Q: Just a month after you began your current job, plague broke out in Surat, India. Did that foreshadow the many global infection threats that you would face?

A: Yes. It was an immediate reminder that by being based in New York City, one of the largest ports of entry to the U.S., we needed to remain alert to outbreaks worldwide. Given the amount of air travel between India and New York City, it was a very real possibility that someone with plague could come here and become ill either en route or after disembarking. We needed to raise awareness about plague among medical providers in the city and think through how we would isolate and manage a suspect case. We had ten calls of suspect plague cases, and though none were confirmed, this experience laid the foundation for our future emergency response planning for other infectious disease issues, including bioterrorism. We started a broadcast fax system for blasting health alerts to all city hospitals—which has transitioned into the Health Alert Network—right before the plague outbreak in India was recognized. It was a very simple technology to start. We had a fax machine that sequentially was able to fax every infection control office, microbiology laboratory, and emergency department in the city. It was very slow—taking most of the night to reach everyone— but that was the technology at the time. It was before email. Now it's evolved to an Internet-based network with the ability to send both fax and email alerts, similar to the Health Alert Networks that are in every other state.

Q: After that, New York City became known for its ability to quickly communicate with medical providers during an emergency.

A: My philosophy is that when a health issue is breaking, I do not want them to read about it in The New York Times or The New York Post the next day. I want them to get the detailed information that they need, and I want them to get it from us. At the same time as our press office is working on press releases, we're working on health alerts. It's not the last thing we do—it's often the first thing we do.

Q: Those public press releases are something else your department is known for.

A: In New York City, we've learned that when breaking news happens, we go public quickly. We don't want to keep secrets—and it's hard to keep things quiet in a city like New York. When the inhalational anthrax case happened in 2001, we announced it around 11:30 at night, soon after the confirmation came in. We've had a couple of rule-out smallpox cases in recent years. We first heard about one from the hospital. As we were on our way out to investigate it, I got a call from CDC: They had just heard there was a smallpox case in New York City—from CNN.

Q: What's the key to good risk communication?

A: It's trusting the public and providing honest information in a clear and effective way. One of the challenges we often face in public health is communicating uncertainty in a way that is understandable. If we tell them that this is a breaking story, we don't know yet what is going on, this is what we're doing to find out, this is when we're going to get back to you—the public can accept that—as opposed to saying, "Oh, don't worry about it, it will be OK." Because it may not be OK a couple hours later. Once you have miscommunication and lose the public's trust and the media's trust, it's really hard to regain.

Q: New York has had more than its share of public health emergencies in the past decade. What were the lessons learned after each—starting, say, with West Nile virus?

A: With West Nile, we began to think about emergency response. We recognized that when a citywide emergency happens, we need to mobilize the full resources of this department. We formalized our incident management system as a direct result of West Nile. With the delayed recognition that West Nile virus was the cause, partly due to the delays in recognizing the connection between the human outbreak and a simultaneous epizootic among birds in the city, we made animal diseases officially reportable to us. At the time, with the exception of rabies, there was no animal disease surveillance that we were directly responsible for. We didn't just change the law—we built relationships and hired a public health veterinarian whose primary role is outreach to the veterinary and wildlife community, not just the clinical veterinarians in the city. So, if they saw something unusual they'd call us. We built a mosquito surveillance and control program—we had none prior to the '99 outbreak. It's become a model mosquito arboviral surveillance and control program.

Q: What did you learn after the 9/11 attacks?

A: The World Trade Center attack was—it's beyond words. The department was activated 24 hours a day. We were doing 12-hour shifts each for the initial weeks after the response, dealing with a multitude of issues, including improving our surveillance for bioterrorism. It was an unprecedented emergency. The incident management system helped. The people who were assigned to the section that I'm the chief of—the surveillance and epi section—knew that they would be needed within minutes of the second plane hitting the towers, and they knew where to come. We had thought through the initial surveillance and epidemiologic response to any public health emergency and had developed a generic checklist. At the time, it seemed simplistic to do, but I can't tell you how useful it was on 9/11. Looking out the window, seeing the buildings on fire, realizing the tragedy that was about to unfold, it helped to have something to guide our initial response.

Q: What about SARS? What would New York City have done if it had seen the same number of cases as Toronto?

A: It's a fair question. Of all the major emergencies that we've gone through, we never went through anything like the SARS outbreaks in Toronto and other cities. We've not had a large contagious disease outbreak to test our emergency response plans. I'm very glad about that. With SARS, we did have a couple of close calls. The physician from Singapore who had been in New York City for an infectious disease conference, and who was recognized as having SARS after leaving the city and during a layover in Germany, easily could have been admitted to a New York City hospital. The woman who ended up being the index case in Toronto transited through the New York City area, and, since she became ill on the flight, she could have been taken off the plane and hospitalized locally. And the original index case in Vietnam was a New York City resident who could have decided to come home for his care; he was too sick to travel, however, and caused a large nosocomial outbreak in Vietnam. SARS, more than anything else, made us think through our plans for contact tracing, isolation, and quarantine. We triaged about 300 calls concerning potential SARS cases. There were only 20 or so that met the clinical case definition—none of them tested positive; it was a pretty broad case definition. But they all had close contacts. So we did experience the challenges in identifying and monitoring contacts for a 10-day period. It was a tremendous effort. We had two suspect cases who needed to be detained legally, because they were not able or willing to isolate themselves in a private residence once they were discharged from a hospital.

Q: New York had a close call. Still, what if the infection had silently broken out, as it did elsewhere? How would your department have handled it?

A: The index outbreak would have been difficult for any jurisdiction to have quickly prevented, because it happened so quickly and it was a newly recognized virus. The one thing that I walked away with, having observed the outbreak mostly from afar, was that SARS was relatively easily managed. The challenge was recognizing a suspect patient quickly so that the person could be immediately placed into isolation. Even countries that didn't have the capacity to utilize airborne precautions were able to stop the outbreak, just by isolating patients and identifying and monitoring contacts, and isolating them if they became ill. With something like SARS, where there was no treatment and no vaccination, the only measures you have are strict adherence to infection control and quarantine precautions. Once patients were discharged home, we mainly monitored them by phone. But when there was a concerning case, there were people who actually went and spot-checked patients at home to make sure they were being compliant with isolation precautions. Especially in these days of cell phones, you never know where somebody is.

Q: How would your department respond to a smallpox case?

A: One confirmed case of smallpox would be considered a bioterrorist outbreak, with the expectation that more cases were likely. If the outbreak were small enough, then our priority would be contact tracing and ring vaccination, because that's how we're going to control the outbreak. We would also begin mass vaccination— because once we have confirmed a smallpox outbreak, we know that somebody has the virus who shouldn't, and we'd need to vaccinate, given the concerns of future attacks. If we had hundreds or thousands of cases, contact tracing would be very labor intensive, and it makes more sense to put all our effort into mass vaccination.

Q: What is the biggest challenge in conceptualizing such a mass vaccination campaign?

A: From a medical perspective, it's realizing you can't do business as usual. You can't have a nurse or clinician at every step. Physicians and nurses tend to ask a lot of questions, and during a mass vaccine clinic, we need to use a triage protocol that optimizes our ability to move people through quickly; only people who have medical issues, such as underlying diseases, would be pulled offline to be seen by a medical provider. We will also need to address the public's concern and expectations for immediate access to vaccine. There's only going to be a small percentage of the public who will need the vaccine immediately, either because they were involved in the initial attack or exposed to a known case. We may not need to do everyone on Day One—but everyone is going to want it on Day One. Another issue is the tremendous need for staff to conduct these clinics citywide. Will staff come in to work at these clinics during a terrorist attack? We conduct drills every once in a while, so that our own staff and our volunteer corps understand their roles and buy into the fact that they would be needed and are comfortable with what they'd be doing.

Q: How would you handle public panic?

A: Preparing a community to be resilient to the mental health impact of terrorism is a challenge. In addition to pre-identifying and training the mental health resources that would need to be mobilized after an attack, there is a need to better educate the public regarding what steps to take after an attack to protect themselves. Israel has probably done a better job than any place in the United States. Many people in Israel know where they need to go for vaccine or antibiotics after a bioterrorism attack. In our emergency management materials to the public, this concept has been mentioned generally, but not in the detail that may be required for the public to know, "OK, this is where I go in my neighborhood." There are positives and negatives about publicizing this level of detail in our response plans. Some people believe that there are things you should keep behind the scenes—because if the terrorists knew, they could interfere with your response. But I've been impressed when I've met people from Israel. Many know what to expect from the government when something happens, and they know what they're supposed to do.

Q: Would mass vaccination be more difficult in New York today than it was during the smallpox outbreak of 1947?

A: I've done a lot of reading about the 1947 smallpox outbreak in New York City; I have a historical talk on the outbreak and how it unfolded from the perspective of my predecessors here at the department. It was a very different time. First, it wasn't a terrorist attack, so it didn't have that flavor on top of the outbreak itself. Second, it was actually a small outbreak, with only 12 cases in the third wave of the outbreak. In retrospect, mass vaccination probably wasn't even needed; contact tracing and ring vaccination would have controlled the outbreak. But at the time the decision was made to vaccinate the whole city, the epidemiology of the outbreak was not yet clear. Third, it also occurred right after the war, at a time when there was trust in government and a sense of civic duty. There was the Civilian Defense Board and other community groups that were geared up for community service and could be leveraged.

Q: How is New York carrying out flu vaccination this year?

A: The primary goal is that we want to direct the vaccine to those who need it most, based on targeting those at highest risk for hospitalization or death due to influenza. We normally provide very little influenza vaccine to the city—most of it is given out by private providers or clinics. But because many private providers don't have vaccine, our public health clinics are very busy in certain parts of the city. Our small immunization clinics weren't meant to have hundreds of people waiting outside. To avoid that, we put in place our point of distribution (PODs) mass vaccination plan. They're not full PODs; it's not like what would happen during smallpox, where we would be attempting to provide vaccine for everyone. But we are using that model to move people through our clinics efficiently. We looked at the Disney model of moving people through lines.

Q: One of America's unsolved public health mysteries is: Who mailed the anthrax letters in 2001? That October 31, a 61-year-old New York City woman died of inhalational anthrax. Did you ever pinpoint how she became infected?

A: I never felt more like a medical detective than when we investigated that case. I took the initial phone report from a very good infectious disease doctor in the city. I suspect that many other physicians may not have thought of anthrax that quickly—in a patient who wasn't in an obvious risk group given what was known about the outbreak up to that point: that is, being someone associated with a high-profile media site or government office. This was a woman who worked in a stock room in a very small hospital in New York City. The physician suspected anthrax based on her clinical presentation, even before the Gram stain came back. In that sense, it was even more impressive than Florida, where they suspected anthrax only after they saw Gram-positive rods in the spinal fluid. This case didn't fit the epidemiology of other cases associated with this outbreak. So the question was: Did she have the same mode of exposure as the other known cases at that point of the investigation—contaminated mail—or was this the beginning of a new outbreak? We also needed to ask: Was she the terrorist? Did she know the terrorist? Or did she accidentally walk by where the terrorists were working? And that is one of our lessons learned: that you can't necessarily predict risk exposures based on the current epidemiology of an intentional outbreak. The terrorists could change the mode or site of exposure. We can't predict what the next attack will be. During this investigation, we needed to determine everywhere this woman had been in the four or more weeks prior to her onset of illness. What was really challenging was that—hers was not an atypical story for New York—she was an older woman who lived by herself, had very few friends and no family in the area. We knew when she was at work, but we could only account for a small percentage of her time outside of work. We very quickly ruled out the worksite as the place of exposure based on active case-finding and environmental testing. As we were ruling out the worksite, we also were trying to find her friends and family, interview people in her neighborhood. We went with pictures of her. We knew she spent time at church, though not just one church, as she seemed to have lots of information about many different churches in her apartment. We knew where she

shopped, based on receipts that we found. So we tried to reconstruct her life, in order to focus our surveillance and environmental testing efforts, but we still could not account for most of her time. We are very confident that the exposure wasn't in her home or work. We also tested the subways. Although we knew by that point that there hadn't been a major release in the subway, it was possible there was a small release in the subway that was botched, and only one person got infected. And we recognized the importance of knowing if someone had tried this, especially to help focus the criminal investigation. We were able to test every station she went in, based on her subway card usage. All tests were negative. We didn't find one spore—which was good. But we needed to think through how we would respond if we did. We actually didn't start testing until we had a plan in place for how we would handle a positive finding, including risk communication to the public and media. At the end of our extensive investigation, we still did not know how she was exposed. She remains, by herself, an unsolved mystery. But then the Connecticut case happened, which led to this theory of cross-contaminated mail. Connecticut actually had an easier task than we did, as their patient's family knew everywhere the patient had been, to help guide their testing. And they still couldn't find a spore, except in the mail distribution center into the area. We knew we also had spores in our distribution center to the hospital and into the city. So in the end, I think that she was exposed to a letter that had been cross contaminated after passing through one of the affected postal distribution centers, but we'll never know for sure.

Q: If you could sit down with President Bush and make three requests for the public health system, what would you ask for?

A: [Pauses.] It's as if I've been given three wishes, and I want to use them effectively. First, there is a need to distribute funds based on risk. In public health, we always use risk-based strategies to target our prevention efforts, and we should do so when it comes to terrorism preparedness. In New York City, we always point out that we were the victims of two of the four planes that struck on September 11, and we received four of the seven known anthrax letters, but we receive a disproportionately small percentage of the federal preparedness dollars. Second, I've always been concerned about the sustainability of the federal bioterrorism funding. Most of what we do in public health isn't done by equipment or supplies that we can buy once, with the costs declining year to year. Public health is a personnel-intensive profession. It requires being able to recruit and retain qualified, motivated staff. We are lucky in New York City that way. We have used our grant funding mostly to hire staff. A lot of health departments didn't make that decision, because they were worried about the sustainability of this funding. The last thing you want to do is hire a lot of people for two to three years, build up a program, and then suddenly lose the funding so that all the efforts fall apart. We decided to take that risk, given the priority that emergency preparedness is in New York City. Third, we need to recognize that not all jurisdictions are the same and that preparedness plans are not "one size fits all." Each jurisdiction needs to determine how best to do things locally. Some federal grant programs have restrictions that don't allow for local capacities and priorities. One example is the City Readiness Initiative. It's new money that is less flexible with respect to how we can use it. This program to plan for prophylaxing the city in a short period of time has come with a lot of oversight and expectations. We've done so much work here on this issue already. We'd like to be allowed to say, "These are our needs; we want to use the money for this." Lastly (my extra wish), I also worry about our federal public health resources, especially the CDC, and hope that the necessary investments to maintain and enhance their capacities are sustained. The CDC has such a long and illustrious history in public health. What makes CDC such a valuable resource to local public health officials like me are the disease-specific experts they've been able to develop and nurture. No health department in the country is going to be able to maintain expertise in all these different diseases—we're generalists. When anthrax happens, I don't have time to pull out 20 journal articles and figure it out myself. I want to be able to call their expert or have access to their reference laboratory expertise. And the lab expertise at CDC is the best, bar none—the histopathologist there who helped us with West Nile and anthrax is one of my heroes, Dr. Sharif Zaki. They have some wonderful disease experts, like Keiji Fukuda for influenza.

Q: New York has invested heavily in syndromic surveillance. What do you see as its pros and cons?

A: We think it has value. Its ultimate worth—being able to identify an outbreak earlier than anything else, resulting in the ability to mobilize a response that significantly reduces morbidity and mortality—has yet to be proven. It may or may not be possible. And there are opportunity costs—depending on what threshold you use in your statistical analyses, you can generate a lot of signals that require investigation and use a lot of staff resources— resources that could be used for other things that are just as important. It's not for everywhere. I came here from Alaska. If I lived in Anchorage, where there are only a few infectious disease physicians, I would likely invest my time in building strong relationships with every ID doc in town. I'm a firm believer in traditional surveillance, but I'm not naïve enough to think that every doctor in New York City knows to call us, cares to call us, wants to call us. There are definitely examples where they haven't. So syndromic surveillance gives me at least a sense of what's going on in the city. The inhalational anthrax case was called in on a Sunday night around 10 o'clock. The next day, we had an alarm in our emergency department syndromic surveillance system around the Upper East Side, where the hospital she worked at was located. We investigated that signal extremely aggressively, because we were worried that it was the beginning of a third terrorist attack—an aerosolized release of anthrax. Obviously, it wasn't—and our signal investigation did not identify any other concerning cases. The signal didn't continue, and every day that syndromic stayed quiet, I felt better that we weren't missing an inhalational anthrax outbreak. The same during SARS: It was very quiet during SARS. I was worried that given the large amount of travel back and forth between here and Asia, we might be missing something. So with several syndromic systems in place by 2003 (emergency department visits, ambulance calls, pharmacy sales, and worker absenteeism), having an ability to keep your finger on the pulse of the city, even indirectly, is something I value. We've shown over the years that syndromic surveillance is really good for detecting citywide viral activity, whether it's flu or norovirus. What it hasn't been as useful for is detecting small outbreaks earlier than through traditional means. The one outbreak we detected that we would not have known about otherwise was a GI outbreak that occurred after the 2003 blackout, most likely caused by people eating food that was spoiled. The only evidence we had of this outbreak was through syndromic surveillance. No one called us. There's an interest now at the federal level in investing in national syndromic surveillance systems. For jurisdictions that don't have anything, there is some value in having it done for you. But I'm concerned about a perception— not necessarily at the federal public health level, but at the political level—that syndromic surveillance is better than traditional surveillance, that you don't want to depend on public health to detect outbreaks, so let's set up systems to do it for them. But syndromic surveillance systems are just smoke detectors—unless you have a public health infrastructure to investigate, it is impossible to determine if an actual outbreak is occurring and what the cause and routes of exposure are. We look at our data seven days a week. If we see anything, we have staff on call to investigate. It requires that commitment. If you don't, it's like placing smoke detectors all over the city but not investing in the fire departments needed to respond when they go off.

Q: Do you ever talk with old timers in public health and compare your job to theirs?

A: There are a lot of ways it's changed. For the most part, public health has benefited from all these recent emergencies—we're more visible. In New York, we've used these emergencies to promote the importance of reporting. The benefit of this is that people call us. But the disadvantage is that people call us—we're busy. It's amazing to me how busy we are compared to the way we used to be, even though we have five times the staff compared to when I first started. I average 200 emails a day. We have several new outbreaks each week. Taking an hour for lunch is a rare event. We are like the fire department within the NYC Department of Health. You have five things that are urgent to do. You walk in your office, and two new outbreaks happen. You have to put those five urgent things aside and deal with the acute outbreaks.

Q: What keeps you in this job?

A: I've accepted and take seriously the emergency preparedness aspects. But what I love about this job is the opportunity to work on and continue to learn about infectious disease epidemiology. New issues come up every week. Every week we do an outbreak review with the entire staff. I've got a very bright, opinionated staff, and we often disagree with each other. And these disagreements often lead to our developing better responses or plans than if we worked alone. Sometimes new people walk into one of our staff meetings, and they think we're not getting along—but we actually get along wonderfully. That meeting is my favorite meeting of the entire week. I run it like resident rounds, where we go over the outbreaks and I ask folks questions. It's just a fun time. Whenever I walk out of that meeting, I think: This is why I'm still here.

- Edward Tatum
- Doctoral students
  - Norton Zinder

Joshua Lederberg, ForMemRS[1] (May 23, 1925 – February 2, 2008)[2] was an American molecular biologist known for his work in microbial genetics, artificial intelligence, and the United States space program. He was 33 years old when he won the 1958 Nobel Prize in Physiology or Medicine for discovering that bacteria can mate and exchange genes (bacterial conjugation).[3] He shared the prize with Edward Tatum and George Beadle, who won for their work with genetics.

In addition to his contributions to biology, Lederberg did extensive research in artificial intelligence. This included work in the NASA experimental programs seeking life on Mars and the chemistry expert systemDendral.

Early life and education

Lederberg was born in Montclair, New Jersey, to a Jewish family, son of Esther Goldenbaum Schulman Lederberg and Rabbi Zvi Hirsch Lederberg, in 1925, and moved to Washington Heights, Manhattan as an infant.[4] He had two younger brothers. Lederberg graduated from Stuyvesant High School in New York City at the age of 15 in 1941.[5] After graduation, he was allowed lab space as part of the American Institute Science Laboratory, a forerunner of the Westinghouse Science Talent Search. He enrolled in Columbia University in 1941, majoring in zoology. Under the mentorship of Francis J. Ryan, he conducted biochemical and genetic studies on the bread mold Neurospora crassa. Intending to receive his MD and fulfill his military service obligations, Lederberg worked as a hospital corpsman during 1943 in the clinical pathology laboratory at St. Albans Naval Hospital, where he examined sailors' blood and stool samples for malaria. He went on to receive his undergraduate degree in 1944.

Bacterial genetics

Joshua Lederberg began medical studies at Columbia's College of Physicians and Surgeons while continuing to perform experiments. **Inspired by Oswald Avery's discovery of the importance of DNA, Lederberg began to investigate his hypothesis that, contrary to prevailing opinion, bacteria did not simply pass down exact copies of genetic information, making all cells in a lineage essentially clones.** After making little progress at Columbia, Lederberg wrote to Edward Tatum, Ryan's post-doctoral mentor, proposing a collaboration. In 1946 and 1947, Lederberg took a leave of absence to study under the mentorship of Tatum at Yale University. Lederberg and Tatum showed that the bacterium Escherichia coli entered a sexual phase during which it could share genetic information through bacterial conjugation.[6][7] With this discovery and some mapping of the E. coli chromosome, Lederberg was able to receive his Ph.D. from Yale University in 1947.[8] **Joshua married Esther Miriam Zimmer (herself a student of Edward Tatum) on December 13, 1946.**

Instead of returning to Columbia to finish his medical degree, Lederberg chose to accept an offer of an assistant professorship in genetics at the University of Wisconsin–Madison. His wife Esther Lederberg went with him to Wisconsin. She received her doctorate there in 1950.

Joshua Lederberg and Norton Zinder showed in 1951 that genetic material could be transferred from one strain of the bacterium Salmonella typhimurium to another using viral material as an intermediary step.[9] This process is called transduction. In 1956, M. Laurance Morse, Esther Lederberg and Joshua

Lederberg also discovered specialized transduction.[10][11] The research in specialized transduction focused upon lambda phage infection of E. coli. Transduction and specialized transduction explained how bacteria of different species could gain resistance to the same antibiotic very quickly.

During her time in Joshua Lederberg's laboratory, Esther Lederberg also discovered fertility factor F, later publishing with Joshua Lederberg and Luigi Luca Cavalli-Sforza. In 1956, the Society of Illinois Bacteriologists simultaneously awarded Joshua Lederberg and Esther Lederberg the Pasteur Medal, for "their outstanding contributions to the fields of microbiology and genetics".

In 1957, Joshua Lederberg founded the Department of Medical Genetics at the University of Wisconsin–Madison. He has held visiting professorship in Bacteriology at the University of California, Berkeley in summer 1950[12] and University of Melbourne (1957). Also in 1957, he was elected to the National Academy of Sciences.[5]

Sir Gustav Nossal views Lederberg as his mentor, describing him as "lightning fast" and "loving a robust debate."[13]

Post Nobel Prize research

Lederberg (right) receiving The National Medal of Science from George H. W. Bush.

In 1958, Joshua Lederberg received the Nobel Prize and moved to Stanford University, where he was the founder and chairman of the Department of Genetics. He collaborated with Frank Macfarlane Burnet to study viral antibodies. **With the launching of Sputnik in 1957, Lederberg became concerned about the biological impact of space exploration.** In a letter to the National Academies of Sciences, he outlined his concerns that extraterrestrial microbes might gain entry to Earth onboard spacecraft, causing catastrophic diseases. He also argued that, conversely, microbial contamination of manmade satellites and probes may obscure the search for extraterrestrial life. He advised quarantine for returning astronauts and equipment and sterilization of equipment prior to launch. Teaming up with Carl Sagan, his public advocacy for what he termed exobiology helped expand the role of biology in NASA.[14]

In the 1960s, he collaborated with Edward Feigenbaum in Stanford's computer science department to develop DENDRAL.

In 1978, he became the president of Rockefeller University, until he stepped down in 1990 and became professor-emeritus of molecular genetics and informatics at Rockefeller University, reflecting his extensive research and publications in these disciplines.[15][16]

Throughout his career, Lederberg was active as a scientific advisor to the U.S. government. **Starting in 1950, he was a member of various panels of the Presidential Science Advisory Committee. In 1979, he became a member of the U.S. Defense Science Board and the chairman of President Jimmy Carter's President's Cancer Panel. In 1989, he received National Medal of Science for his contributions to the scientific world. In 1994, he headed the Department of Defense's Task Force on Persian Gulf War Health Effects, which investigated Gulf War Syndrome.**

Awards and accolades

Impact crater Lederberg in Xanthe Terra on Mars

- The Benjamin Franklin Medal for Distinguished Achievement in the Sciences of the American Philosophical Society, 2002.[17]
- The Presidential Medal of Freedom, 2006.
- In Lederberg's honor, the 87 km diameter large impact crater in Xanthe Terra on the surface of Mars was named in the year 2012.[18]

Personal

Lederberg married fellow scientist Esther Miriam Zimmer in 1946; they divorced in 1966. He married psychiatrist Marguerite Stein Kirsch in 1968. He was survived by Marguerite, their daughter, Anne Lederberg, and his stepson, David Kirsch. [...]

In Memoriam: Joshua Lederberg (1925–2008)

James M. Hughes* and D. Peter Drotman†

Source - Emerging Infectious Diseases • www.cdc.gov/eid • Vol. 14, No. 6, June 2008 981 / Source : [HG00BT][GDrive]

The world of emerging infections lost a valuable friend and inspiring leader earlier this year with the death of Joshua Lederberg. The globally recognized scientist, educator, national and Presidential scientific advisor, and Nobel Laureate died of pneumonia on February 2, 2008, at the age of 82. Dr Lederberg's early work on bacterial genetics virtually established the discipline of molecular biology, earning him a Nobel Prize in Physiology or Medicine in 1958, when he was only 33 years of age. His contributions paved the way toward understanding microbial adaptation, including the development of antimicrobial drug resistance and the implications of these evolutionary changes for clinical medicine and public health. Equally impressive are his public service contributions; he served as a science advisor to 9 US presidents.

Dr Lederberg began his exploration of bacterial genetics as a doctoral student at Yale University, where he forged new paths and gained prominence in the developing field. Over the next 30 years, he held academic posts and chaired new genetics departments at the University of Wisconsin and Stanford University. In 1978, he joined Rockefeller University as its president. Over the next 12 years, his accomplishments and successes in this position were a testimony to his scholarly accomplishments and leadership skills; he remained affiliated with the university for the rest of his life. He offered science policy advice not only to 9 US administrations but also to the National Aeronautics and Space Administration and the Department of Defense. In addition to the Nobel Prize, his numerous prestigious awards included the National Medal of Science in 1989 and the Presidential Medal of Freedom in 2006.

To those of us working in the field of emerging infectious diseases, Dr Lederberg will be most remembered for his critical role in recognizing the threats posed by emerging and reemerging infections and their implications for public health and national security. He is well known to readers of Emerging Infectious Diseases (EID) as a contributor to the journal (1,2) and for his leadership as co-chair with the late [Dr. Robert Ellis Shope (born 1929)] (3) of t**he Institute of Medicine (IOM) Committee on Emerging Microbial Threats to Health, which produced the 1992 report Emerging Infections: Microbial Threats to Health in the United States (4) (Figure 1, panel A). [PDF : https://www.ncbi.nlm.nih.gov/books/NBK234855/pdf/Bookshelf_NBK234855.pdf]** This landmark report defined the concept of emerging and reemerging infections, identified factors contributing to disease emergence and reemergence, and emphasized current and future challenges posed by infectious diseases. The report also highlighted deficiencies in our nation's public health infrastructure and made recommendations on the need to strengthen surveillance systems, address new areas of research, provide multidisciplinary training for the next generation of scientists and public health workers, and establish new and enhance existing disease prevention and control programs. EID owes its genesis to this report.

[HG00BU][GDrive]
Dr Lederberg

Figure 1 : [HG00BV][GDrive]
A) Emerging Infections: Microbial Threats to Health in the United States (4), a report of the Institute of Medicine (IOM) Committee on Emerging Microbial Threats to Health, published in 1992. B) Microbial Threats to Health: Emergence, Detection, and Response (8), a report of the IOM Committee on Emerging Microbial Threats to Health, published in 2003.

Drs Lederberg and [Dr. Robert Ellis Shope (born 1929)] were extremely effective in communicating the committee's observations and recommendations to the scientific, public health, and public policy communities, generating broad and renewed interest in infectious diseases. **The report had a profound impact on the Centers for Disease Control and Prevention (CDC), the National Institute of Allergy and Infectious Diseases, the Department of Defense, and other federal agency programs involved in addressing emerging infectious disease threats.** The report's emphasis on the need for interdisciplinary strategies and coordinated approaches led to the establishment of the Working Group on Emerging and Re-emerging Infectious Diseases under the auspices of the National Science and Technology Council Committee on International Science, Engineering and Technology. This Working Group was chaired by CDC Director David Satcher, and its deliberations led to vastly improved communication and collaboration among many federal agencies (5).

For CDC, the impact of the IOM report and Dr Lederberg's contributions were substantial. CDC worked with partners to develop new domestic and global strategies to address emerging infections, including specific efforts to respond to the IOM recommendations. Dr Lederberg served as an advisor on the development of these strategies (Figure 2), the first of which was published in 1994 (6), with an update 4 years later (7). **From 1994 through 2004, CDC's funding for infectious diseases grew nearly 200-fold, from $1 million to >$190 million, enabling development and implementation of numerous programs to build epidemiology and laboratory capacity and improve preparedness and response capacity for infectious diseases and other health threats.** Examples of these programs include the Emerging Infections Programs with activities such as FoodNet and Active Bacterial Core surveillance; the International Emerging Infections Programs; the Epidemiology and Laboratory Capacity for Infectious Diseases cooperative agreement; the Emerging Infectious Diseases Laboratory Fellowship Program; this journal; and the International Conference on Emerging Infectious Diseases, first held in 1998 with Dr Lederberg serving as the inaugural plenary speaker (2) and, most recently, in March 2008.

As an advocate for improvements in information systems and transparency, Dr Lederberg enthusiastically supported innovative approaches that included the establishment of ProMED and the Global Public Health Information Network. Internationally, he served as an advisor to the World Health Organization (WHO) on the creation of its Emerging Infections Program and personally advocated the need for establishing this program with WHO's then director general, Dr Hiroshi Nakajima.

Figure 2 - [HG00BW][GDrive]
Institute of Medicine co-chair Joshua Lederberg (left) in conversation with James M. Hughes, director, National Center for Infectious Diseases, Centers for Disease Control and Prevention (CDC), during a meeting in 1993 with expert consultants on development of the first CDC emerging infectious disease strategy.

Figure 3 - [HG00BXU][GDrive]

Dr Lederberg also served as co-chair, with Dr Margaret Hamburg, of a second IOM committee that produced a follow-up to the 1992 report. Microbial Threats to Health: Emergence, Detection, and Response was published in March 2003 (8), less than 1 week after WHO issued its first global health alert in response to the outbreak of severe acute respiratory syndrome (SARS). This report had a broader global perspective than the 1992 report and identified additional factors contributing to disease emergence, reemergence, and global spread. **The report also anticipated many issues that the 2003 SARS outbreak so starkly illustrated, including the need for increased collaboration among the human and animal health communities, a recommendation now supported by the One Health Initiative (9).** The 2003 report's cover (Figure 1, panel B) depicts an artistic rendering of influenza virus, reflecting Dr Lederberg's longstanding interest in influenza research and his concern about national and global preparedness for the next pandemic.

As a charter member of the IOM, Dr Lederberg was the driving force behind the creation of its Forum on Emerging Infections (now the Forum on Microbial Threats), steering it effectively as chairperson through 2002. Consistent with his approach, the forum comprises representatives of the medical, academic, public health, veterinary, agricultural, environmental, national security, and pharmaceutical sectors. An important part of his legacy, the forum continues to address a broad range of issues in an interdisciplinary setting on a regular basis, recently focusing on vector-borne and zoonotic diseases and the potential impact of climate change on infectious diseases. As Josh liked to say, there is an ongoing confrontation with the microbial world involving "our wits versus their genes." The forum held a workshop in May 2008 on microbial evolution and coadaptation in honor of Dr Lederberg (www.iom.edu/CMS/3783/3924/52347.aspx).

On a personal level, I (J.M.H.) first encountered Professor Lederberg in the late 1960s, when I was a medical student and he was the chairman of the Genetics Department at Stanford. His stature and accomplishments were legendary, and we were in awe of him. Over the course of my CDC career, I was fortunate to have many interactions with Josh and to greatly benefit from his insightful questions, keen observations, and constructive comments. He was very approachable and consistently available to discuss a broad range of issues, having an uncanny ability to readily span from basic science, to applied science, to public health, to policy, and to national security. He was a mentor, friend, and colleague to many.

For me (D.P.D.), Dr Lederberg was a great friend and early champion of EID, supporting the journal from its first issue in 1995. He helped us obtain credibility by recruiting editorial board members, supporting our application for early listing in national databases, and encouraging authors and reviewers of the nascent journal. We profiled him briefly when we published his plenary lecture at the inaugural International Conference on Emerging Infectious Diseases (Figure 3) (2) and compared his far-seeing work to that of Rudolf Virchow, one of the founders of modern medical science, because both wrote reports that called the attention of central governments to the manifold contributors to the web of causation of emerging diseases (10).

Dr Lederberg will be remembered for his scientific vision and contributions, his integrity and credibility, and his unwavering commitment to advocate for the highest quality science and evidence-based public policy. He was a firm believer in the need for scientists and public health officials to communicate clearly and concisely with policy makers and the public on scientific and public health issues. His influence and impact reached broadly, across areas of expertise and around the world. He will be greatly missed.

Biographies

Dr Hughes is professor of medicine in the Division of Infectious Diseases, Department of Medicine, School of Medicine, and professor of public health in the Hubert Department of Global Health, Rollins School of Public Health, at Emory University. His research interests include factors contributing to infectious disease emergence and antimicrobial resistance; global infectious disease surveillance and public health capacity building; and water-related diseases and the impact of water, sanitation, and hand hygiene interventions on health.

Dr Drotman is editor-in-chief of the journal Emerging Infectious Diseases at CDC.

Connected with ONA's Andrew Marshall "for decades"

See https://phe.rockefeller.edu/wp-content/uploads/2020/05/Andrew-Marshall-and-Classics2RU.pdf

"Andrew Marshall and Classics: A Remembrance Jesse H. Ausubel Forthcoming in Remembering Andy Marshall, Andrew May (ed.) In 1999 I was pondering a millennial book project titled The World's Progress exploring both what follows a forward arrow (science and technology) and what does not (human biology and behavior). Among my most valued interlocutors was Joshua Lederberg, a Nobel-winning Rockefeller University geneticist with a subtle, expansive mind and eidetic memory. Josh had been in conversation with Andy Marshall for decades on many topics, and was corresponding with him then about whether successful warriors have higher Malthusian fitness and the changing attributes of martial success, including effective leadership, technical prowess, and instinctive behaviors. Josh sensed an interesting match, and connected us, and thus began my own conversation with Andy, which would last almost 20 years. One naturally associates martial and Marshall. Martial stems from Mars, the Roman god of war, while Marshall in fact is a Norman name for persons who tend horses, but I associate Andy with the classics. The word "classics" derives from the Latin adjective classicus, meaning in ancient Rome "belonging to the highest class of citizens."1 By the second century CE, literary critics used the word to describe the highest-quality writers. Andrew W. Marshall lived for classics. He sought to grasp the broad meaning of the entirety of history, the ultimate design of the world. Such timeless understanding is not found in committee reports. Andy understood that most great intellectual achievements of the kind he valued came from individual minds. Andy's capacity to read and listen enabled him to voyage in space and time. For Andy space and time united. History was a set of developments of ideas in time, while geography was the development of a set of ideas in space. He always seemed at home in a room where maps covered the walls. At the same time, he understood that history employs people to do its work."

The Nobel Prize Winners continued

by Joshua Lederberg

I would say that peace, and the quality and quantity of the human population loom very large — the problems they pose have to be solved if we are to sustain any hope for the future.

As to finding the means to cope with these problems, my viewpoint may be biased. However, I feel that the universities, which should be the centers of independent thought and learning, cannot continue to do their jobs unless their financial strength and autonomy can be sustained and drastically improved. Not only do they lack some of the resources they need for bold experimentation and planning, but the time and effort of many of our leaders in these institutions is seriously diverted from creative thought by constant attention to financial problems. The same warning made to college presidents who spend the greater part of their time in soliciting funds, applies in varying degrees to our faculty members as well.

There have been several excellent books written recently which state these concerns more fully and eloquently than I could myself; "Brave New World Revisited," by Aldous Huxley, "The Next Hundred Years," by Harrison Brown, and "The Open Mind," by J. R. Oppenheimer.

Dr. Joshua Lederberg, 35, received the Medical award in 1958 for his studies of virus-induced genetic changes in bacteria. He now heads the Stanford Medical Center's Genetics department

"The Universities cannot continue to do their job unless. . . ."

Euphenics Gains in Study of Humans

IMPROVEMENT OF THE HUMAN RACE may be achieved much sooner by controlled "euphenics" than by "eugenics," according to Dr. Joshua Lederberg, head of the genetics department at the Stanford University School of Medicine.

In a paper that has attracted worldwide interest, Lederberg predicts that methods of controlling human development—euphenics—will be available sooner than most biologists had expected. This is likely to be an earlier approach toward altering the physical characteristics of human beings than proposed attempts to change the hereditary makeup of individuals by selective breeding.

The technique of euphenics is now in the experimental stage, with work on the transplantation of kidneys to extend life. Lederberg believes that methods can be learned to transplant other organs and even to regulate the size of the brain by prenatal or postnatal intervention.

ALGENY, by Jeremy Rifkin. New York: Viking, 298 pages, $14.75.

By JOSEPH J. MARON

If the Industrial Age can be thought of as the search for a better mousetrap, then the age we are now entering, the Age of Algeny, may be called the search for a better mouse.

You won't find the word "algeny" in the dictionary — yet. Coined by Dr. Joshua Lederberg of Rockefeller University, it refers to the coming transformations of the biotechnical revolution. Biological engineering is about to give man the power of redesigning every species on the planet, including his own. No power since the harnessing of fire will so affect our lives.

This is the warning of Jermy Rifkin, economist, social scientist and philosopher who, in his latest book, examines the steadily emerging implications spawned by the marriage of computer technology and the biological sciences.

"The final goal of the algenist is to engineer the perfect organism. The 'golden state' is the state of optimal efficiency. Nature is seen as a hierarchical order of increasingly efficient living systems."

Every age develops a cosmology or "world-view" as a way of justifying its behavior. Darwinism provided the cosmological justification for the Industrial Age. Consider how neatly capitalism's free enterprise and communism's class struggle fit into Darwinism's two great paradigms, natural selection and survival of the fittest.

The fruits of biological engineering will be both real and astonishing. Corporations like General Electric already assure us, "We bring good things to life."

"The problem," says Rifkin, "is that biotechnology has a beginning but no end. Cell by cell, tissue by tissue, organ by organ, we give up our bodies as we give up our political power, a piece at a time."

In his final chapter Rifkin posits "two futures, two choices. An engineering approach to the age of biology or an ecological approach. The battle between bioengineering and ecology is a battle of values."

Rifkin's passionately felt and eloquently argued choice is "to end our long, self-imposed exile; to rejoin the community of life. This is the task before us. It will require that we renounce our drive for sovereignty over everything that lives; that we restore the rest of creation to a place of dignity and respect. The resacralization of nature stands before us as the great mission of the coming age."

Rifkin's writing is crisp and clear with a touch of measured urgency. His analysis is appropriately repetitious as he approaches a complex subject from several directions. The text is well-documented, the bibliography extensive and up-to-date.

This is a book aimed at the general reader because Rifkin believes the subject is much too important to be left to the "experts."

(Joseph J. Maron teaches art at Meredith College.)

PREDICTIONS PROVE WRONG

Infectious diseases now third leading killer

An aging population, AIDS partially blamed

Emerging diseases: A program to avert the possibility of devastating epidemics is proposed.

By Mike Toner
STAFF WRITER

Infectious diseases, once thought to have been vanquished by antibiotics and modern public health measures, are on the rise again in the United States.

The Centers for Disease Control and Prevention reported Tuesday that deaths from infectious disease rose 58 percent between 1980 and 1992. As a result of the surge, infectious diseases have surpassed strokes and accidents as a leading cause of death and now rank third behind only heart disease and cancer.

Although some of the increase is due to an aging population and the emergence of AIDS, researchers say deteriorating U.S. public health programs, increased virulence of disease-causing organisms and microbes' growing resistance to antibiotics have played a key role in the sudden turn of events.

"Despite historical predictions that infectious diseases would wane in the United States, infectious disease mortality has actually been increasing in recent years," the CDC's Dr. Robert Pinner said Tuesday in Washington.

He said the 58 percent increase — 39 percent even after being adjusted to reflect the aging population — represents only a part of the problem. Nonfatal infections, such as the childhood ear infections that cause 30 million doctors' visits a year, are increasing, too.

Pinner's report was part of a major news briefing on the threat of emerging diseases, sponsored by the American Medical Association, which Tuesday called for a concerted worldwide effort to combat emerging diseases and antibiotic-resistant organisms.

In a commentary in the current issue of the Journal of the American Medical Association (JAMA), Anthony Fauci, director of the National Institute of Allergy and Infectious Diseases, warned that without concerted action, the world would face "the worst effects of what is inevitable in the future — more emerging microbes and possibly more devastating epidemics."

In the same issue, Nobel laureate Joshua Lederberg said the "unprecedented mixing of people" caused by increased international travel has created a "tinderbox" for the spread of once-isolated diseases such as Ebola fever.

Lederberg, a microbiologist at Rockefeller University, proposed a five-point program to deal with emerging diseases that includes heightened global surveillance of disease outbreaks, improved sanitation and expanded research on new drugs and vaccines.

But two groups of researchers reported new evidence that the spread of resistant microbes is, in part, being abetted by the medical establishment's own overreliance on antibiotics as a cure-all for infectious diseases.

On the rise

Infectious disease is now the third leading cause of death in the United States. A comparison of the leading killers in 1980 and 1992:

Leading causes of infectious disease deaths in 1992:

Respiratory tract infections	77,336
AIDS	33,581
Blood infections	19,667
Kidney/urinary infections	12,399

Source: U.S. Centers for Disease Control and Prevention

STEPHEN CAMPER / Staff

Researchers at the Ohio State University Medical Center report in JAMA that "excessive antibiotic use appears to be the driving force" behind the spread of penicillin-resistant strains of streptococcus bacteria, which annually causes 500,000 cases of pneumonia, 7 million middle ear infections and 3,000 cases of meningitis.

Although other antibiotics are still effective against the germ, penicillin's dwindling efficacy makes treatment more difficult. The researchers say an education program for doctors and patients is needed to "reduce the demand and use of unnecessary antibiotics."

In the same issue of JAMA, researchers in Iceland say a concerted two-year effort to reduce antibiotic use in the nation's day care centers has reduced the number of resistant ear infections, which had increased steadily since 1988.

Under the new program, Icelandic doctors have been advised not to routinely prescribe antibiotics at the first signs of ear or respiratory infections. Instead, they watch patients more closely and order antibiotics only if it appears the infection is not going to resolve itself — as it often does.

"The greatest reduction in antimicrobial use has been in the youngest age group, where it matters the most," says Karl Kristinsson of Reykjavik's National University Hospital.

Fauci said he personally opposed restricting doctors' ability to prescribe antibiotics in the United States, but he said new guidelines on the use of antibiotics are needed.

"We need to have more education, counseling and guidelines for physicians on how to use antibiotics," he said.

ACCESS ATLANTA

Dr. David Satcher, director of the CDC, will be online Sunday to answer your questions about the CDC, its changing mission and other topics explored in a special Atlanta Journal-Constitution report coming this weekend. Talk live with Satcher from 5 to 6 p.m. in the Atlanta Chat room. *Members, jump: Chat, select Access Atlanta, then Atlanta Chat Room.* Information, **Page A2.**

New health threats feared if climates shift

Complex links: Scientists urge intensified studies of the potential effects of Earth's rising temperature.

By Jeff Nesmith
WASHINGTON BUREAU

Washington — Global warming — expected to push the Earth's temperature to its highest level in millions of years in the 21st century — could cause an unprecedented spread of some infectious diseases, scientists warned Tuesday.

Diseases such as dengue and malaria, traditionally confined to tropical areas, may move into temperate zones if mosquitoes, rats and other creatures that carry them expand their territories as climates change, said a team of researchers from Johns Hopkins, Harvard and George Washington universities.

On the other hand, diseases that seem to prefer cooler climates — especially those carried by ticks — may decline, the researchers said in an article in the Journal of the American Medical Association.

To deal with emerging epidemics, physicians and public health officials will have to understand complex linkages between environment and disease, said Dr. Jonathan Patz of Johns Hopkins, one of the article's authors.

He said the "potential human health impacts . . . on future generations" call for increased efforts to come to grips now with uncertainties of climate change and health.

The article was part of an international collection of more than 200 articles on emerging and re-emerging microbial threats being published in January issues of medical journals worldwide.

Despite disagreements over the rate and precise causes of global warming, many climate experts are convinced that the buildup of so-called greenhouse gases in the atmosphere is pushing up the overall temperature of the planet.

According to some projections, the Earth's temperature will increase by 5 degrees Fahrenheit by the year 2100.

Mosquito-borne diseases, such as malaria, dengue and viral encephalitis, are among the ailments most sensitive to climate, Patz said during a news conference Tuesday.

For example, a virulent dengue strain known as "breakbone fever" spread during the unseasonably warm summer of 1988 to areas of Mexico where it usually does not appear, Patz said.

He said female *Aedes aegypti* mosquitoes, which carry the disease, are typically smaller in hotter climates and must feed more often to produce their eggs. That means they bite people more often, increasing the odds of the disease spreading.

At the same time, the dengue virus becomes more infectious in warmer temperatures, Patz said.

In addition to heightening the spread of mosquito-borne diseases, climate change could lead to higher incidence of waterborne infections and toxin-related illnesses as a result of increases in sea surface temperatures, Patz said.

Herbert H. Lehman Dies in New York; Mourned by Jewry; Funeral Sunday

Herbert H. Lehman, twice elected to the United States Senate, Governor of New York State for 10 years, first director-general of the United Nations Relief and Rehabilitation Agency, and one of the foremost active leaders in many Jewish causes for many years, died suddenly here today. He was 85.

Funeral services will be held Sunday at 1. p.m., at Temple Emanu-El, and interment will be private. Mr. Lehman's remains will lie at the Universal Chapel, 52nd. St. and Lexington Avenue, tomorrow from 1. p. m. to 10 p.m., and Saturday from 10 a.m. to 10 p.m. Messages of condolence and grief, from every major Jewish organization, secular, religious and philanthropic, poured into the Lehman home and office here as soon as his death was announced. (See Page 5 for statements of condolence.)

The former Senator was universally acclaimed as the "elder statesman" of American Jewry, as well as one of the most outstanding Americans remaining in public life carrying on the traditions of President Franklin D. Roosevelt.

Throughout his long career in public office and in leadership of the affairs of the Democratic Party, Mr. Lehman never divorced himself from Jewish affairs and from activities supporting Israel. He affirmed many times the principle that he must be as free to participate in social welfare and other affairs affecting Jews as he was free to serve the general community on all levels–statewide, nationally and internationally.

Herbert Lehman was born in New York City in 1878, the scion of a German family that had immigrated to the United States in 1848, engaging in the textile business. He studied at Williams College, graduating in 1899, entered the cotton goods business, later became a partner in the banking firm of Lehman Brothers. He severed his connection with that company when he began his first term as New York State Governor in 1933.

WAS RE-ELECTED THREE TIMES AS GOVERNOR OF NEW YORK STATE

In 1917, when the United States entered World War I, young Lehman went to Washington and became an aide to Assistant Secretary of the Navy Franklin D. Roosevelt. Later, he was commissioned a captain in the U.S. Army. For his outstanding work, he was given the U.S. Distinguished Service Award. He retired from active army service in 1919, as a colonel on the General Staff.

In 1920, Mr. Lehman became known as one of the most active supporters of Alfred E. Smith. When Mr. Smith was elected Governor he appointed Mr. Lehman as mediator of industrial disputes in the garment industry, a trade in which Jewish workers as well as Jewish industrialists figured most prominently. In 1926, Mayor James J. Walker, of New York, commissioned Mr. Lehman to make a study of the city's finances.

When Franklin D. Roosevelt was nominated for Governor of New York in 1928, Mr. Lehman became Mr. Roosevelt's running partner in that campaign, as candidate for Lieutenant Governor. They were elected. When Governor Roosevelt was absent from the State, Mr. Lehman was Acting Governor. Roosevelt and Lehman ran together again, being elected by overwhelming votes. When Mr. Roosevelt ran for his first term for the Presidency in 1932, the reigns of the State were handed over to Mr. Lehman. He was re-elected three times, serving three terms of two years and one term of four years.

WAS FOUNDER OF J. D. C.; ACTIVE IN WORK FOR JEWS IN PALESTINE

From 1949 to 1957, Mr. Lehman served two terms as United States Senator, continuing in Washington his espousal of the New Deal policies which he had helped President Roosevelt develop.

Mr. Lehman entered social welfare work early in life, shortly after graduating from college, becoming an advisor to a boys' club at the Henry Street Settlement, one of the country's earliest institutions of the kind, operating chiefly on New York's lower East Side. He was one of the founders of the Joint Distribution Committee, and after the end of World War I, he became chairman of the Reconstruction Committee of the JDC. He also became a trustee of the Hebrew Sheltering Guardian Society, and of the Bureau of Jewish Social Research.

He displayed his interest in the Jewish settlement in Palestine early in his career, becoming vice-chairman of the Palestine Economic Corporation. When Israel became a State in 1948, Mr. Lehman continued to support the Jewish State. In 1958, he was general chairman of the United States Committee for the celebration of Israel's tenth anniversary. At his death, he was honorary general chairman of the National United Jewish Appeal; honorary chairman of the Joint Distribution Committee; and one of the topmost leaders of the Greater New York UJA. He was active for many years in the leadership of the American Jewish Committee, and was honorary vice-president of the AJC. He was also, for 15 years, honorary president of the American Friends of the Alliance Israelite Universelle.

DIRECTED AID TO MILLIONS OF REFUGEES AFTER WORLD WAR II

As first director-general of UNRRA, he established that United Nations Agency's successful activities toward aiding many millions of displaced persons, refugees, and others who suffered from the adverse social, economic and humanitarian consequences resulting from the broad devastations caused during World War II. He had acquired much of his experience aiding his work as head of UNRRA both through his welfare work in Jewish organizations and through his office as the U.S. State Department's director of foreign relief and rehabilitation operations in 1942.

In more recent years, although showing his advanced age, Mr. Lehman continued his activities both in Jewish causes and in general politics. Until a year ago, Mr. Lehman frequently appeared at New York street corners, during hot political campaigns, speaking vigorously on behalf of the election of reform candidates. Mrs. Lehman nearly always accompanied him in all of his public appearances, even standing behind him on shaky street-corner stands as he delivered political speeches.

WAS DIRECTOR OF NATIONAL ASSOCIATION FOR ADVANCEMENT OF COLORED PEOPLE

Among his many interests was an undeviating one in freedom and equality for Negroes in the United States. He was a member of the board of directors of the National Association for the Advancement of Colored People. He had been scheduled to receive honors tonight at a dinner planned by the National Committee Against Discrimination, where A. Philip Randolph, one of the country's outstanding Negro leaders, was to have shared in those honors.

Mr. Lehman was also among the topmost, active lay leaders in the Jewish Theological Seminary of America; the New York Foundation; Visiting Nurse Service; Institute for Advanced Study; Surprise Lake Camp; Franklin D. Roosevelt Memorial Foundation; the National Conference of Christians and Jews; the Jewish Child Care Association. He was honorary president of the World ORT Union; a member of the Council of the New York University School of Law; a national board member of the American Association for the United Nations; a member of the national council of the Boy Scouts of America.

For many years, Mr. Lehman was the recipient of many outstanding awards, citations and honorary degrees from many sources and institutions of higher learning. In 1941, he received the honorary degree of doctor of laws from the Jewish Theological Seminary. He was the recipient of at least 15 other honorary degrees from many colleges and universities, ranging from Yeshiva College to Fordham University (Catholic).

The **J. Lehrenkrauss Corporation** was a Brooklyn, New York based mortgage-servicing business which became insolvent in 1934.[1] On January 25, 1935, Julius Lehrenkrauss, 67, the head of the firm, was convicted of mail fraud in the sale of $1,600,000 of preferred stock. The company is noteworthy because of the crimes it committed. Its failure happened during the Great Depression when credit lending agencies were strained due to deflation and a weak economy in the United States in the early 1930s.

Government prosecutors alleged that the business was bankrupt in 1932 and 1933, at the time the stock was sold.[2] Lehrenkrauss received a suspended sentence because of his advanced age. Two partners and a former salesman for the firm were given active prison terms. [3]

J. Lehrenkrauss & Sons, a banking and brokerage enterprise, was a subsidiary of the J. Lehrenkrauss Corporation. It was located at 359 Fulton Street (Brooklyn) in December 1933.[4]

BORO HOSPITAL TRUSTEES NAME NEW MEMBERS

Julius Lehrenkrauss Elected by Wyckoff Heights Institution

Julius Lehrenkrauss was unanimously elected one of the trustees of the Wyckoff Heights Hospital at a meeting of the Board of Trustees held yesterday afternoon at the instiution.

Mr. Lehrenkrauss has been a member of the Hospital Society for many years and but recently he again manifested his interest for the institution by donating $5,000 for the new annex and madernization fund.

President John Welz announced that he new addition, practically completed now, has ample floor space connecting the present maternity department, which will increase the bed capacity by at least fifteen more beds. The administration offices are being moved into new and larger quarters and will be a complete unit.

A complete renovation of the present hospital, which has now reached its twenty-eighth year, is under way.

Jacob Bartscherer, chairman of the Nurses' Training School Committee, said that the quota of student nurses is now almost filled and that further applications to enter the training school would be received during this month for the next term. A high school education is required for entering.

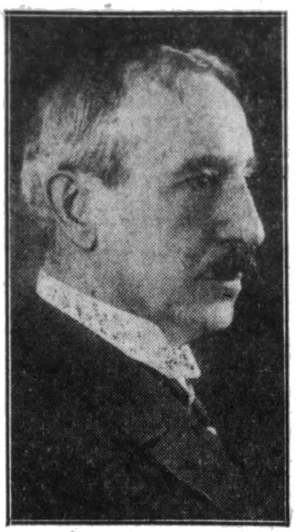
EXTENDING SERVICE



Julius Lehrenkrauss

J. Lehrenkrauss Expands Service

J. Lehrenkrauss' Sons, Inc., one of the oldest financial houses in Brooklyn, and which on the first of next month celebrates its 55th anniversary, will open a New York City branch office at 85 Maiden Lane, on May 1, Julius Lehrenkrauss, president of the Lehrenkrauss Corporation, announced today.

1933-04-27-the-brooklyn-eagle-pg-28-clip-lehrenkrauss

"The extension of our facilities at this time is a clear indication of what we expect of business activity in the future," Mr. Lehrenkrauss stated. "Our firm has seen several periods of depression come and go, and has been in business long enough to know that each such period is merely starting ground for further progress.'"

Coincident with the opening of the Manhattan office the Lehrenkrauss firm also announces its appointment as suburban general agents and Metropolitan agents for the Allemannia Insurance Company of the Crum & Forster group, suburban general agents for the Insurance Company of the State of Pennsylvania and also Brooklyn agent for National Fire Insurance Company of Pittsburgh.

J. Lehrenkrauss' Sons, Inc., was founded on May 1, 1878, starting business in a humble office in a storeroom in Brooklyn. The past 55 years has seen steady and consistent growth. The company occupies its own five-story office building at 359 Fulton St. For many years it has served as general agent in Brooklyn for American Eagle Fire Insurance Company, Camden Fire Association, Franklin Fire Insurance Company and the Maryland Fire Insurance Company. It is also general agent for Columbian National Life Insurance Company.

David Howells will be in charge of the New York City office.

LEHRENKRAUSS CORP. IN RECEIVERSHIP SUIT

Bankruptcy Petition Also Filed Against Partners in Brooklyn Mortgage Company.

An application for the appointment of a receiver to conserve the assets of the Lehrenkrauss Corporation of 359 Fulton Street, Brooklyn, and four subsidiary companies, was made in a suit in equity filed against the corporation in the Federal Court in the borough yesterday. Judge Marcus B. Campbell reserved decision until this morning.

At the same time, and in the same court, a petition in bankruptcy was filed against Julius Lehrenkrauss, Charles F. Lehrenkrauss and J. Lester M. Lehrenkrauss individually and as general partners in the Lehrenkrauss Corporation and against Herman Richter and Julius Kaiser, individually and as special partners in the concern. The persons named have twenty days in which to contest the charge of insolvency.

The papers in both actions were filed by Archibald Palmer, attorney of 2 Lafayette Street, Manhattan, who also asked the court for authority to conduct a hearing under the bankruptcy laws into the affairs of the Lehrenkrauss Corporation. This request was granted.

The Lehrenkrauss concern has been in business in Brooklyn since 1847. It dealt in mortgages, conducted a travel bureau and did a general banking and insurance business. The subsidiary corporations of the concern are the Lehrenkrauss Mortgage Title and Guaranty Company, Universal Tours, Inc. Omnis Corporation and J. Lehrenkrauss & Sons, Inc.

Mr. Palmer said yesterday the assets of the Lehrenkrauss Corporation were approximately $12,000,000 and the liabilities about $3,000,000, besides guarantees of an unknown amount on real estate mortgages.

The suit in equity was brought on behalf of William Greenbaum of Montclair, N. J., and the application for a receiver was concurred in by the Lehrenkrauss Corporation through its counsel, Kenneth McEwen, of 102 Maiden Lane.

1933-12-15-nytimes-lehrenkrauss-home

LEHRENKRAUSS HOME BOUGHT BY HIS FIRM

Charles Lehrenkrauss Tells at Hearing of Financing for Him by Banking House.

J. Lehrenkrauss & Sons of 359 Fulton Street, Brooklyn, against which a petition in bankruptcy was filed last week, built a $55,000 Garden City home for Charles Lehrenkrauss, member of the banking house, Mr. Lehrenkrauss testified yesterday at an inquiry into the company's affairs before Louis R. Bick, special commissioner, in Brooklyn Federal Building.

The company also paid the taxes, assessments and interest on a $30,000 mortgage on the house, Mr. Lehrenkrauss, a nephew of Julius Lehrenkrauss, head of the companies, said. The charges and the total cost were to be charged up to his past and prospective profits in the concerns, he said, adding that participating certificates were sold by the concern in the mortgage.

Walter B. Smith, a salesman who sold some of the stock of the Lehrenkrauss Corporation, admitted that the address given for "Karl Ritter," the mythical man described in literature of the Lehrenkrauss Corporation as the "one man the depression missed" because he invested in Lehrenkrauss stock, was his own.

John Kaiser of Oceanside, L. I., said he resigned as a special partner in the house Sept. 11, after being connected with it for forty years, "because I had a million headaches for a year before I left."

For aiding in the sale of $2,500,000 of preferred stock of the Lehrenkrauss Corporation, which he was engaged to help form, James J. Fradkin, president of the Brooklyn Commerce Corporation, was to receive 10 per cent of the amount taken in, Mr. Fradkin testified; $1,611,000 worth was sold. He said he resigned about Sept. 1.

Lehrenkrauss Tells of Loans Made by Banks

MUSIC, DIPLO

Much Switching of Collateral When He Was Pressed for Payment

Continued from Page 1

$200,000 mortgage his firm held against the Shore Road Theater, Bay Ridge.

Participations Sold

Before pledging this mortgage, Palmer developed, $192,000 of participations in it had been sold to the public.

Palmer asked if before posting the mortgage as collateral the witness had made any effort to ascertain if participations in it had been sold. He said he had not, because it had been "only a special short-time loan that was soon paid off."

Bank Kept Mortgage

Q. What happened to the mortgage then? A. The bank refused to return it. They insisted that I sign a new collateral agreement covering my other loans that would add this mortgage to the collateral already posted.

Says Vom Lehn Is After Rents

Max M. Wolff, former manager of the heal estate division of the Lehrenkrauss organization was another witness of the day. He testified that Vom Lehn is currently "endeavoring to collect the rents on 15 properties belonging to the Omnis Corporation, a Lehrenkrauss realty holding corporation.

Properties on which Vom Lehn is "endeavoring" to collect the rents were enumerated by Wolff as 15 and 21 E. 88th St.; 155-13, 155-15, 155-17, 155-21, 155-23 and 155-29 Bergen Landing Road, Richmond Hill; 3, 5, 7, 9 and 11 Parkway Court; 49 E. 24th St., and an apartment house at Archer Place and 149th St., Jamaica.

Palmer said only the representative of the Brooklyn Federal Court had the right to collect rents now on these or other Lehrenkrauss properties.

Old Folks Homes Mulcted

Last evening's session ended with the questioning of Herman Richter, a special partner, regarding the sale of mortgages and mortgage participations to German orphanages, homes for the aged and sick benefit societies.

At least two, according to Palmer, are shown by the firm's books to have been sold participations in mortgages that previously had been sold to other individuals either as whole mortgages or in the fractional participations.

These, characterized by Palmer as "victimized institutions, were named as the the Marien Heim, 876 Ocean Parkway, a home for old German couples, and thePlattdeutsche Altenheim Gesellshaft, Hempstead, L. I

Julius a Trustee

Julius Lehrenkrauss is a trustee of the Marien Heim, Richter testified. He said it holds $25,000 of participation that Palmer asserted "appears to be no better than a partnership promissory note."

The institution at Hempstead holds $150,000 of Lehrenkrauss mortgage certificates.

While asserting that there were "a great many other" German societies and German organizations that bought Lehrenkrauss paper, Richter could recall "at this time" only three more, the addresses of which he did not remember.

He named them as the Amt Stolzenauer Verein, a sick benefit society, which holds $10,000; the Hanover Verein, another sick benefit, $8,000, and the Amt Severner, a Brooklyn German club, whose holdings he did not know. Richter said he was himself a member of the Amt Stolzenauer Verein.

Was 'Whole Business'

"Julius Lehrenkrauss," said Palmer, "has repeatedly testified that he was kept so busy signing guarantees that he did not read and checks that he did not examine that he had no time for anything else. Just what part did he take in the affairs of the House of Lehrenkrauss?"

"He was the entire business," replied Richter. "He had exclusive charge of the financial end."

Referring to testimony given by Richter at a prior hearing that was devoted to the operations of the Omnis Corporation, a realty holding concern of the partnership, Palmer continued:

Q. You testified that you were only a figurehead president of that corporation and signed whatever papers were put before you to sign? A. That is right.

Q. I show you the minutes of a directors meeting of Dec. 31, 1932, which lists you as having attended and as elected a director for the ensuing year; were you there? A. I was not.

Not at Meetings

Arrivals on Italian line's Atlantic speed queen Rex, which docked today. Photograph shows (left) Janet Olcott, adopted daughter of the famous Chauncey, a pianist in her own right

simply asked Vom Lehn to go and ask the bank to lend the money. At that time, according to Julius, the bank already held collateral for "between $200,000 and $300,000 of loans advanced."

When Vom Lehn returned and advised the money would be advanced. Julius then testified he had one of his employes give him a list of mortgages available for discount and had sent one or more of these mortgages, of a face value of $75,000, to the bank as collateral.

"Did you first ascertain if any participations had been sold against those mortgages?" questioned Palmer.

"No," was the reply.

The second time the witness was threatened with contempt proceedings was when he had stared in silence for 12 minutes by the court clock at the minutes of a meeting of his organization whereon was recorded that he had attended.

"It's about time you answered whether or not you attended that meeting," Palmer then exclaimed, reiterating the substance of the question, asked when the minutes were handed the witness.

Commissioner Bick demanded that the question be answered. He repeated his demand and noted the elapsed time. After he had threatened the contempt citation, Julius replied that he had not attended the meeting.

Only Signed Papers

Thereafter, the witness met question after question with the response that their substance concerned matters that were attended to by the 100 persons in his employ. Repeatedly he stated that all of the time spent in his offices at 359 Fulton St. had been devoted to signing papers. Prior to 1932 he said his nephew, Charles, or Richter or various employes were in control. He asserted that he had nothing to do with the hiring or firing of his employes, that having been done by Charles, "but I had complete confidence in my employes." After 1932 he said the entire business was run by James J. Fradkin, sales manager of an issue of $1,600,000 of Lehrenkrauss Corporation preferred stock that was sold the public.

"If I understand you right," said Palmer in conclusion, "you claim Vom Lehn fixed the value of all Lehrenkrauss properties and the amount of mortgages to be put on

directors' meeting of Jan. 23, 1933, which shows you to have been present and bears your signature, certified to, as present and having presided; were you there? A. I was not.

Q. You would sign minutes of meetings without having attended? A. Julius or Herman Hammel would give me the minutes to sign and because Julius told me to, I'd sign them—Julius was the boss.

Q. You'd sign anything, even if it wasn't true, because he'd tell you? A. Yes.

Julius, aging head of the house, had preceded Richter on the stand. Twice Commissioner Bick threatened to cite him for contempt of court for failing to answer questions. In both instances he had offered successions of answers in no wise responsive to the questions, then had lapsed into protracted silences which Palmer denounced as "putting on an act."

The first instance concerned a loan which Richard Vom Lehn had negotiated for J. Lehrenkrauss & Sons with the Kings County Trust last Oct. 3. It had been for $75,000. Palmer wanted to know how Vom Lehn had come to negotiate the loan.

After being permitted to leave the witness stand and go into another room and confer with his attorney, Julius returned and said he had

them, others sold the mortgages and participations and all you ever did was sit in the back and sign whatever was given you. Is that right?"

"Yes," was the reply.

Kaltenborn Re
Criticism,

Despite a request made to the Federal Radio Commission to discipline him for his statement that it was just as impossible for communists in Nazi Germany to receive a fair trial "as it is for the Scottsboro boys to receive a fair trial in Alabama," H. V. Kaltenborn, radio news commentator and former associate editor of The Eagle, today reiterated that statement and pointed to the record to support him.

Thomas E. Knight Jr., Attorney General of Alabama, had made the request to the commission, declaring that he knew the Negro defendants accused of assaulting two white girls "had a scrupulously fair trial."

"I explained," Mr. Kaltenborn said,

3 NAMED TRUSTEES FOR LEHRENKRAUSS

Close to 3,000 Persons Try to Get Into Meeting of the Bankrupt Firm's Creditors.

AFFAIRS FOUND MUDDLED

C. J. McDermott Calls Them 'Most Intricate Mess' in His 50 Years' Experience.

Charles J. McDermott, Charles Kriger and Frederick S. Martyn were elected trustees yesterday for the bankrupt banking and mortgage firm of J. Lehrenkrauss & Sons, 359 Fulton Street, Brooklyn, at a creditors' meeting in the Brooklyn Federal Building. Between 2,500 and 3,000 men and women tried to squeeze into a court room built to accommodate about 200 and those who failed to get in jammed the corridors on the seventh floor.

Archibald Palmer, attorney for a group of creditors at the bankruptcy hearings, advised those who had made wills designating members of the Lehrenkrauss firm as executors to get the instruments back and change them.

Mr. Palmer asked Theodore Stitt, referee in bankruptcy, to turn over to United States Attorney Ameli all testimony taken at the hearings on the activities of the firm, with the request that the Federal attorney consider the possibility of prosecution on the grounds of misuse of the mails. Mr. Stitt replied that this would have to be done under the bankruptcy laws.

Mr. McDermott told the creditors it was impossible as yet to determine the exact amount of the liabilities and assets of the firm.

"At the start," he said, "we were ready to accept every statement made by the House of Lehrenkrauss. To our surprise we found the picture hard to unravel. We cannot make a report at this time. It is the most interwoven, intricate and hopelessly muddled mess I have ever seen in more than fifty years' experience at the bar, but I believe something will be saved for the creditors."

Mr. Stitt announced that creditors would have until June 24 to file claims against the concern. He warned them not to sell their claims to persons who might offer to buy them for a small sum and advised them to consult the trustees for any information they desired.

The next meeting of the creditors will be held Jan. 29.

1943 (Dec 04) - Julius Lehrenkrauss dies

The New York Times

SATURDAY, DECEMBER 4, 1943

Man Who Dealt in Millions Dies in Poverty; Lehrenkrauss, Ex-Banker, Served in Prison

Julius Lehrenkrauss, once head of a leading Brooklyn mortgage and investment house, died late Wednesday after six years of poverty, following his release from Sing Sing Prison, where he served three years of a five-to-ten-year sentence for grand larceny.

The once wealthy and influential banker had been living in precarious circumstances, working at odd jobs, and death came as he left his furnished room at 149 St. Mark's Avenue on his way to work in McNulty's Shipyard, 9 Summit Street, Brooklyn. His pay was 85 cents an hour. His age was 76.

As head of "the House of Lehrenkrauss," he once dealt in millions. In 1933 his firm went into bankruptcy and soon afterward he was arrested on the grand larceny charge. In March, 1934, he was convicted of the theft of $32,000 in a mortgage after pleading guilty.

On the day he was sentenced, March 7, 1934, County Judge Algeron I. Nova, in Brooklyn, presiding at the trial, declared:

"Hundreds of thousands of dollars were taken in from poor German families that had faith in the name of Lehrenkrauss. They believed their bonds were as safe as United States bonds and they got waste paper."

Lehrenkrauss presented a distinguished appearance throughout the trial, appearing in striped trousers and wing collar. The day after sentence was pronounced he was handcuffed to a burglar and sent to prison. One year after entering prison he was assigned as secretary and record clerk in the Sing Sing school.

With $20 in his pocket he left the prison on parole, announcing that he would make a fresh start in life. He worked in various menial tasks until two months ago when he was taken on as a firewatcher in the shipyard. He lived alone and his sole survivor is a son, Lester, 35.

While he was in Sing Sing in 1935, he and four others of his defunct organization were brought to trial in the Brooklyn Federal Court on charges of using the mails to defraud as the result of the sale of $1,600,000 in preferred stock of the Lehrenkrauss Corporation, a holding company for the Lehrenkrauss enterprises. He, Charles Lehrenkrauss, a partner, and James J. Fradkin, a salesman, were convicted. The old man got a five-year suspended sentence. He appeared at the trial in striped trousers, wing collar and cutaway coat and gave his address as "Sing Sing prison."

Julius Lehrenkrauss was cremated yesterday in Fresh Pond Cemetery, Middle Village, Queens.

BROOKLYN'S MAN OF THE WEEK:

Trump the Builder Plays Mothers as Ace Cards

By RICHARD J. ROTH

Mother's Day is more than a once-a-year proposition so far as Fred Trump is concerned. The builder of Brooklyn's two new housing giants, Shore Haven at Bensonhurst and Beach Haven at Brighton, tries to keep mother in mind the other 364 days as well. And with good reason.

Trump has found that, while it may be papa who pays, it's mama who makes the decision on where the money is going in more than four out of every five apartment rentals.

"In 85 percent of our rentals the final decision has depended on the woman's say-so," the 44-year-old former carpenter's helper pointed out in his field office at the rapidly rising Beach Haven development. "The husband cares only about the convenience of transportation and whether his wife likes the apartment."

Emphasis on Labor Saving

With those statistics firmly in mind Trump built the 1,350-apartment Shore Haven development and is rushing to completion the 1,800-unit Beach Haven development with more than a nod in the direction of what he terms "the woman's point of view." The emphasis is on labor-saving conveniences and other features designed to appeal to the distaff side of the family, particularly to mothers with young children.

Fred C. Trump

At Beach Haven, for example, Trump has provided a building and 6,000 square feet of land at a $1-a-year rental, including heat, for the Board of Education. A unique kindergarten and first-grade school exclusively for residents of the development will be opened.

Baby-Sitter Service

Other innovations include an organized baby-sitter service, using girls from Abraham Lincoln High School, which is directly opposite the Brighton Beach development at Ocean Parkway and Shore Parkway. Also planned are a "courtesy car" bus service to the beach for those who prefer to ride, and ultra-violet clothing driers in the basement laundry rooms in each of the 23 buildings, thus eliminating the roof driers which, the builder declared, are "left over from an old-fashioned era."

A modern $300,000 shopping center, with 14 stores and a 250-car parking area, also is about to rise on Beach Haven property. Other parking spaces will be provided on the landscaped grounds, as well as playground and bench areas, with only 20 percent of the project covered with buildings. Heated garages, with a total capacity of 650 cars, are being constructed in the basement of every building.

'Renting Honeymoon Over'

Why all this consideration for the residents? an amazed veteran of the housing shortage might ask, and in this case, did. The answer, according to Fred Trump, is simple:

"We realize that the renting honeymoon is over. We're attempting to make a real step forward to attract the type of tenant who will appreciate these extra services. Our innovations, we hope, will make for a happier housewife, a happier home life, and a resultant happier community."

Fred Trump was born in the Bronx on Oct. 11, 1905, the son of a former Klondike restaurant operator. After the gold rush of '98 had subsided the elder Trump had dabbled on a small scale in the real estate business.

Started in Queens Village

The Trumps moved to Woodhaven shortly after Fred was born and he attended Richmond Hill High School. At 18, following graduation, he took a job as a carpenter's helper, supplementing this practical experience with courses in building construction three nights a week in the Y. M. C. A. Then he went out on his own.

The first Trump homes began to go up in Queens shortly afterward, about 400 or 500 one-family units in the Queens Village area. Then, after 1932, when home building was at an ebb, Trump was awarded, in Federal Court, the mortgage servicing for the bankrupt Lehrenkrauss financial empire.

This took up much of his time for a year. And he operated one of the first self-service food markets, building it up into a profitable large-volume business before leasing it to a well-known food chain.

Sold 78 Homes in 20 Days

In 1935 Fred Trump moved his operations to Brooklyn, picking a site at Avenue H and Kings Highway. On Nov. 10 he completed the model home; within the next 20 days he sold all 78 of the $3,990 homes, a price which was then about half the average rate.

Those 78 homes have been followed by close to 2,500 in the last 15 years in Flatbush, Manhattan Beach and Bensonhurst. During the war he built 1,400 apartments for war workers at Norfolk and Newport News, Va., and Chester, Pa. Shore Haven was opened in June, 1948, and Beach Haven, begun last November, will be completed in a phenomenal year's time.

Much of Trump's success in his Brooklyn building can be attributed to his pioneering in the field of pile-driving, which permits construction on filled-in land. Beach Haven, for example, is built on land that was once marshy. It is atop 55-foot creosoted logs, each of which can sustain a 25-ton load, five times the required burden.

The good-looking builder was married in 1936 to a Scottish-born girl whom he met at a party. They have five children, ranging in ages from 2 to 13.

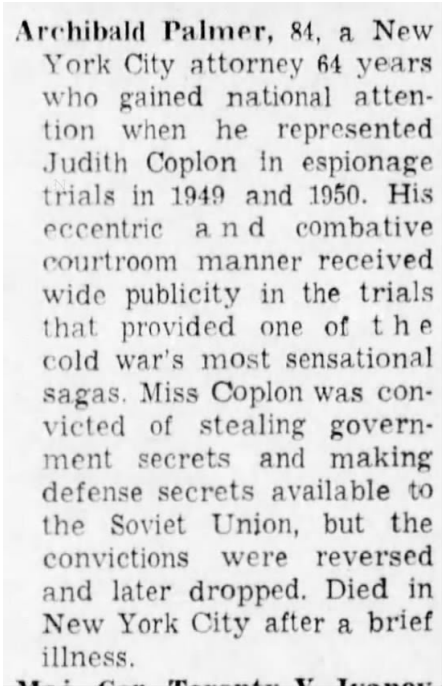
1969 (June 21) - Archibald palmer - Handled Russian espionage cases in 1949 and 1950



Archibald Palmer, 84, a New York City attorney 64 years who gained national attention when he represented Judith Coplon in espionage trials in 1949 and 1950. His eccentric and combative courtroom manner received wide publicity in the trials that provided one of the cold war's most sensational sagas. Miss Coplon was convicted of stealing government secrets and making defense secrets available to the Soviet Union, but the convictions were reversed and later dropped. Died in New York City after a brief illness.

Saved Wikipedia (Dec 30, 2020) for "F. Thomson Leighton"

[HK004N][GDrive]

Frank Thomson "Tom" Leighton (born 1956) is the CEO of Akamai Technologies, the company he co-founded with Daniel Lewin in 1998.[1] Akamai has become the top content delivery provider in the 21st century with the arrival of dedicated techs. As one of the world's preeminent authorities on algorithms for network applications and cybersecurity, Dr. Leighton discovered a solution to freeing up web congestion using applied mathematics and distributed computing.[2]

He is on leave as a professor of Applied Mathematics and a member of the Computer Science and Artificial Intelligence Laboratory (CSAIL) at the Massachusetts Institute of Technology (MIT). He received his B.S.E. in Electrical Engineering from Princeton University in 1978, and his Ph.D.in Mathematics from MIT in 1981.[3] His brother David T. Leighton is a full professor at the University of Notre Dame, specializing in transport phenomena.[4] Their father was a U.S. Navy colleague and friend of Admiral Hyman G. Rickover, a founder of the Research Science Institute (RSI).

Dr. Leighton has served on numerous government, industry and academic advisory panels, including the Presidential Informational Technology Advisory Committee (PITAC) and chaired its subcommittee on cybersecurity.[5] He serves on the Board of Trustees of the Society for Science & the Public(SSP) and of the Center for Excellence in Education (CEE), and he has participated in the Distinguished Lecture Series at CEE's flagship program for high school students, the Research Science Institute (RSI).

Awards and honors[edit]

In 2018, Leighton won the Marconi Prize from the Marconi Society for "his fundamental contributions to the technology and establishment of content delivery networks".[6] In 2017, Leighton and Lewin were inducted into the National Inventors Hall of Fame, for Content Delivery Network methods.[7] He was the first winner of the Machtey Award in 1981 and is a Fellow of the American Academy of Arts and Sciences and a member of the National Academy of Engineering. In 2008, he was appointed as a member of the United States National Academy of Sciences. In 2012 he became a fellow of the American Mathematical Society.[8] He received the IEEE Computer Society Charles Babbage Award in 2001. He was elected as an ACM Fellow in 2018 for "his leadership in the establishment of content delivery networks, and his contributions to algorithm design".[9]

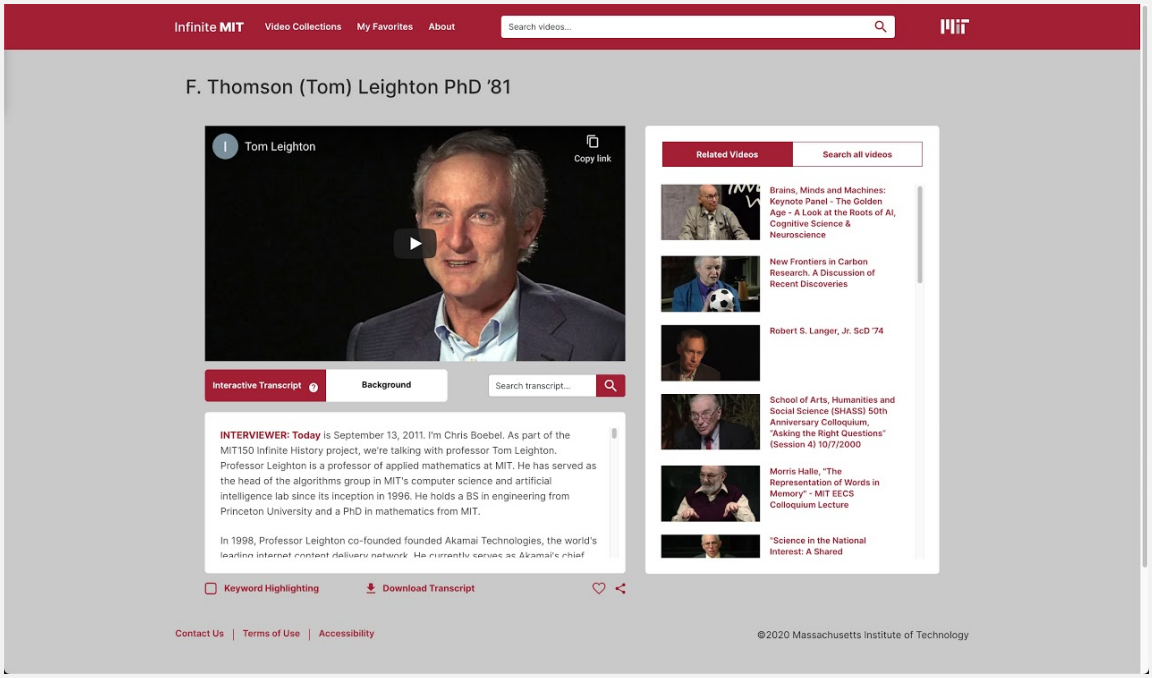
2011 (Sep 13) Interview - F. Thomson (Tom) Leighton PhD ’81

INTERVIEWER: Today is September 13, 2011. I'm Chris Boebel. As part of the MIT150 Infinite History **project,** we're ta

Transcript (below) - [HE003S][GDrive] (video - https://youtu.be/gWJW4TAquCI)



[HE003T][GDrive]

INTERVIEWER: So let's start at the beginning, as it were. Tell me a little bit about where you grew up, how you grew up, your life as a as a kid.

LEIGHTON: I grew up in Arlington, Virginia, right near Washington, DC. My dad was in the Navy, worked in the nuclear power program, and then continued that work, working for Admiral Rickover as a civilian when he got out of the Navy. My mom spent most of her time raising us kids and then became a librarian when they needed to get some extra cash to be able to afford college for myself and my brother. It was a nice environment for growing up. Parents cared a lot about us and a lot about our education. Made sure we had all the best opportunities they could afford for us. Went to good schools. My high school, Washington-Lee High School, was a very good public school. That's before the days when they had Thomas Jefferson in the Alexandria area, which is now a magnet school for all the science and math talented kids. And then went to Princeton for college. Majored in electrical engineering, computer science, and then found my way to MIT for graduate school in applied mathematics.

INTERVIEWER: So tell me a little bit about growing up as a kid. Were there moments that stand out in your memory as realizations that you had a particular aptitude for math or science?

LEIGHTON: I always just loved mathematics and really liked science. As far back as I can remember, there was no question that's what I wanted to do. I suppose when I was little enough, I wanted to be a train conductor. But once I got past that stage, I just wanted to do math, and science related to it. I didn't really know what that meant in terms of careers until much later. But it was very natural for me to evolve along the graduate student research track, become a postdoc, become a professor, because I just liked doing that stuff. I had a lot of help as a kid, starting with my parents, of course, but also through organizations like science fairs, the then Westinghouse Science Talent Search, now the Intel Science Talent Search, the International Science and Engineering Fair, teachers that went out of their way to help, and actually people in industry that went out of their way to give me special access to large-scale computing back then. Of course, the computers back then fit in my wallet today. But it was a special to have access when I was a kid to the old UNIVAC machines or whatever. And I was able to use the computing cycles to do research on number theory, which I enjoyed a lot as a kid. And that helped encourage me in the direction of mathematics and applied mathematics and computer science in later life.

INTERVIEWER: So when you were a senior, you were a finalist in the Westinghouse Talent Search, which I recall from my days in high school-- I think I went to high school before it was the Intel Talent Search-- was a pretty big deal. Tell me about that experience and how it shaped you.

LEIGHTON: It was a fantastic experience. You get to meet 40 other kids, or 39 other kids, with similar interests. It's where I met Eric Lander, who's probably somebody else you've interviewed here. In fact, that year Eric won first place, and I won second place. And of course, I've known Eric to this day. I met other folks there, in fact, including one of my college roommates my first year at Princeton. And I know several of those folks today. We're still friends. So it's a wonderful experience to get together with other kids who have similar interests in science and math and who really care about it. And so today, in fact, I'm now a trustee for SSP, which is the new version of Science Service, which used to run the Westinghouse Science Talent Search. And today, Science for the Society & the Public runs the Intel Science Search. So it's a chance to give back a little bit in thanks for the impact that they had on my life.

INTERVIEWER: I also wanted to follow up on something you mentioned, this sort of early exposure to computers and early programming experiences. Tell me a bit more about that. Where did that happen? What kinds of problems were you dealing with? I have a vague memory of this myself. Were these stacks of punch cards you were working with?

LEIGHTON: I am old enough to remember the paper tape, believe it or not, in my junior high school. And we were pretty fortunate to have any computer in junior high back then. And then it evolved into punch cards. My science project then was looking at some very famous conjectures. The first is Goldbach's conjecture. And about 300 years ago, Goldbach conjectured that every even number is expressible as the sum of two prime numbers. A prime number being a number like 3 or 11 that has no factors other than itself or 1. So for example, 12 = 5 + 7. And he conjectured that it was true for all even numbers, you could write them this way. And so I was trying to prove that. Now, I didn't realize then I had no chance of proving that, because a lot of serious mathematicians have been working on this for centuries. But I did computer studies that gave evidence to a theory of if you viewed numbers probabilistically, that the bigger the number gets, the more representations it has as the sum of two primes. And if you argue that primes are somehow random, then you could make an argument that says, yeah, it should be true for all of them. That's not a proof, but it gives-- today I'm not even sure I would say it gives evidence that it's true, but back then I thought it did, as a high school student. But doing the analysis involved programming with large computers back then to get this evidence that would back up the theory. The other problem was, again, a long, open question of number theory, which is that there's an infinite number of pairs of primes, p and p + 2, where p + 2 and p are both prime. They're called twin primes. And I was trying to give evidence for the fact that in fact there were an infinite number and that, in fact, for any arithmetic sequence of primes, either the pattern occurred once, or it would occur an infinite number of times, which was a new conjecture. I'm not sure anybody really picked up on that conjecture, but it's something I worked on in high school. And it got me introduced to computers and what they could do. And I learned how to program. And that's where people in government and industry reached out to me and gave me access. I remember a fellow named Carl Hammer who was the senior chief scientist at UNIVAC in Washington way back when. And because he was the chief scientist of a big computer company, he had special access to state-of-the-art equipment, and he lent me that access, which was wonderful. Here I am, 16 or 17, and I had access to the state-of-the-art computing back then.

INTERVIEWER: So what about the importance of those kinds of mentors or that kind of encouragement in encouraging your early career and, I guess, by extension other people's careers too? We'll talk later about your own work as a professor and a teacher.

LEIGHTON: I think mentors are incredibly important. They become role models. You want to become like them. You see career paths. And they help you. They encourage what you're doing, which, I think, is good for kids to be thinking about math and science problems and spending a lot of time working on them. I think that's really great. It helps launch them on a track as a researcher or as a scientist and mathematician. And they tackle real problems more seriously later in life. And it can make a difference that way. So I think mentorship is very, very important.

INTERVIEWER: Were there other important mentors to you that we haven't talked about, maybe in your high school years or at Princeton before MIT?

LEIGHTON: Yeah, I think there's a series of people. I remember there was a teacher of graph theory at Princeton. And he just was a great teacher, and he had a love for the field. And it becomes infectious. And you just love working extra hard to show him what you can do and to be able to have a dialogue with him. So it's very motivational. Here at MIT, there were some excellent professors-- good teachers, good advisers. And you want to become like them when you grow up. And that makes a big difference. It helps you evolve into the next level by seeing people that you have a lot of respect for and that are really good at what they do.

INTERVIEWER: So at Princeton, you majored in engineering. Tell me a bit about that, how that became your focus rather than mathematics or other directions you might have gone.

LEIGHTON: Well, a couple of things. First, I was afraid of real analysis. And if you were a math student, you had to take real analysis. Math at Princeton was

a little scary. Pretty tough. And it was very pure. And my interests were more on the discrete side of mathematics, which MIT is great at, the world's best at. They had their token discrete mathematician, who's the guy who I liked as my mentor at Princeton at that time. And I found that the kinds of things I liked best actually were done in the computer science or EECS department back then. And in fact, that's where I started learning about theoretical computer science-- algorithms, complexity theory. And you can almost think of it as a branch of discrete mathematics. It's in computer science, but the tools are all mathematics, and the kinds of problems are all discrete mathematics problems, combinatorial kinds of things. And so I really gravitated there, and they had a very flexible policy. You could do pretty much whatever you wanted. And so I just ended up going there for my degree and ended up getting lots of graduate courses and just taking everything they had, because it was so much fun. It was really great stuff.

INTERVIEWER: And then you made the decision to come to MIT for graduate school. Tell me about that.

LEIGHTON: MIT is the best place in the world for discrete mathematics and the best place in the world for theoretical computer science, so it was a perfect fit. And when I chose between the two, I decided when I came to MIT to do the applied math track. So I didn't do math as an undergrad but did do as a graduate student. Also, I had some encouragement from my father when I was an undergrad to go the engineering route. And somewhat joking, I think he felt that if you're doing mathematics, you'll never get a job. Engineering, well, that's okay. He himself, of course, was an engineer. I'm exaggerating a little bit. But then, by the time I got to graduate school, at that point I'm doing research anyway, and it doesn't really matter anymore to me. I'm not thinking about getting a job. I'm thinking, okay, I'm going to be a professor. Well, that's a job, but it's not the same kind of job. And so let's do the applied math thing, because that's where folks like Danny Kleitman, Gary Miller, Len Adleman, Richard Stanley-- those guys were all in the math department. And that was just a fantastic fit, because I could do everything. I could do the math I liked. I could do the computer science I liked in that department. It was very flexible. And I had a great time doing that.

INTERVIEWER: So what year roughly did you come to MIT, and what was the environment like at the time just generally on campus but also within your department?

LEIGHTON: I came in '78. I did notice when I came, there was tension in the department between within the applied math between the discrete side and the continuous side- - the guys that do partial differential equations and so forth. And this was relevant because we had to pass our oral exams. And the prior year, all the students on the discrete were failed. And being on the discrete side, that was of some concern. And I do remember that was a big issue, and there was a tension between the two sides of the department. Now, I think they since got beyond that. I think things on campus, I don't really have any recollection one way or the other. It was a fun experience. It was good. I really liked it. I could do research. Great faculty. Good colleagues. That was long past all the stuff with kicking ROTC off campus and all those kinds of things. So the campus, I think, was very peaceful when I came. The question was, are you going to win your intramural softball game this weekend? That was the extent of it, as I remember anyway. Maybe I was just oblivious.

INTERVIEWER: Is there a way of explaining for someone like me discrete versus continuous?

LEIGHTON: Continuous is calculus. You do an integral for discrete mathematics. You compute the area under a curve-- sorry, in continuous mathematics. In discrete mathematics, it's summing a series of numbers. What's the sum of 1 + 2 + 4 + 8 + 16? That kind of thing. You have differential equations on the continuous side. On the discrete side, you have a recurrence, that the running time for the algorithm on an input of size n is twice the running time it takes for an input of half the size plus n more steps. And the techniques really down deep, there's similarities, but the actual day to day is different from continuous mathematics and discrete mathematics. Counting things is discrete. How many ways are there to put five red balls and six green balls and pick from them-- that kind of thing is discrete. Continuous is complex analysis, real analysis, calculus, and stuff like that. Proof methods are different. You use induction when you're doing discrete mathematics. You use different approaches when you're doing pure or continuous mathematics.

INTERVIEWER: And what is it about discrete mathematics that you found attractive and appealing, that kind of clicked with you?

LEIGHTON: I found I could get my arms around it better. The definition of discrete mathematics is it's dealing with numbers, things that are countable. Doesn't mean they can't be infinite, but they're very constrained in how they're infinite, like 1, 2, 3, 4, 5, 6 to infinity. That's very concrete, get your arms around. Continuous mathematics, there's an uncountable number of points in the unit sphere. I found it conceptually more challenging to get my mind around it. I liked it. It was good, but I liked the discrete side much better. Also, when you get into the applications, things like computer science and theoretical computer science, it's the discrete mathematics that matters. And so you can have a chance to have impact with your applications from discrete mathematics. Structures like graphs, points and lines, or points and edges that connect them, nodes, arcs to represent communication problems or network flow problems-- that's all in discrete mathematics.

INTERVIEWER: And what kind of problems really attracted you as a grad student? What kinds of things were you working on and really drove your interest?

LEIGHTON: I think they primarily revolved around graphs-- using networks to model things and proving facts about them. Some were just pure graph theory. And most came up in the context of a computer science problem of some kind. Ultimately I wrote my thesis on problems-- the field then was called very-large-scale integration, or VLSI. And in practice, that referred to the design of tiny microprocessors on chips and how to lay out the transistors in the wires to fit as much as you can on the device. In my mathematical version of that world, it was all about taking a graph and embedding it in a grid in a way that was efficient somehow. And that's pure mathematics at that point. So that was sort of the focus, the sweet spot when I was a graduate student.

INTERVIEWER: And who were you working with, both in terms of faculty and even other grad students at that time? Who leaves an impression in your mind as being a particularly important influence?

LEIGHTON: Gary Miller was my adviser, and he was a great adviser. He was very giving, very unselfish. He would get me good problems to work on. He'd encourage me. He'd listen to me. He'd give me good ideas. He wouldn't even try to put his name on the paper. He wouldn't try to take credit in any way. He was just a really good guy. And that's a great role model. If you have nice parents, better chance you're going to be a nice parent yourself. So that was great. Danny Kleitman, fantastic influence. Again, super guy. Really nice. Very smart. Great to talk to. Great problems. Very encouraging, supportive. Always putting the student first. So they were probably the two largest influences on me as a graduate student, and they were both in applied math. Len Adleman comes to mind. I worked a little bit with Len. He left MIT pretty early on. He was a great teacher. And so that's the kind of thing you try to emulate on the teaching side of things. He made material clear. He made it be interesting, made you want to think, wow, this is important. I want to work on this stuff. And of course, you got guys like Ron Rivest. Very famous, doing huge things. Sort of a funny story. Today there's a thing called the RSA algorithm. It is used for the encryption on everything you do online. So very important thing. Early on, it was very revolutionary. Nobody thought that, oh, that can't be a good idea to base an encryption protocol on the difficulty of factoring numbers. Before it even became public, when I was a undergrad, I was at the then National Bureau of Standards, now called NIST. And because of the Westinghouse Science Talent Search, I got a summer job there. And I was working with a mathematician there. And the RSA paper was sent. The government got their hands on it, and they wanted to evaluate it. And so it went to the mathematicians at the National Bureau of Standards. And so my summer project was to evaluate the RSA algorithm. It's a little scary the government is relying on some undergrad

in a summer job to do the evaluation, but it was really cool. And then later, I come to MIT years later, and, wow, there's Ron Rivest. Pretty cool.

INTERVIEWER: Did you share your evaluation?

LEIGHTON: My evaluation was that I sure as heck didn't know how to break it, that it wasn't clear that anybody would know how to break it. But also there was no proof that it was unbreakable and that if we relied on it, people would try to figure out how to factor better and that this could cause a problem. And in the end, people have learned how to factor better. And so instead of using hundred-digit keys they were doing back, now you got to use thousand-digit keys, because people have got better factoring algorithms. And still nobody knows how to break it, but there's still no proof that they won't figure out how

INTERVIEWER: So it's just a matter of staying ahead?

LEIGHTON: Today? Yeah, that's right. But a lot of people have been thinking about it now, so factoring seems pretty tricky.

INTERVIEWER: So tell me a little bit about making the transition then to being on the faculty at MIT.

LEIGHTON: That means you've got to teach and you've got to get research grants. Now, I had, I would say, a very cushioned experience joining the faculty, because I got a postdoc first. And it was a two-year postdoc. And after the first year, I joined the faculty, but I had the postdoc, so it meant that I didn't have to teach, but I was on the faculty. So that gave me a breather to help adjust. And then when I did start teaching, the field, the community at large, started getting pretty excited about the field I was working in-- large-scale networks and doing large-scale parallel computation and distributed computing. The area I had gravitated to became hot out there. And so I got to create a graduate course on that material. So it was based on the field that I cared most about, and it took me a ton of time. I spent a week for every hour and a half of lecture. But it was very worthwhile for me, because it was my field of interest. And you never really learn something until you have to teach it, at least I find. So it gave me a chance to really learn even at a deeper level what was happening in my field. And so a lot of good research came out of the fact that I was teaching this class. Students that were interested in doing research in this new field took the class, ended up doing research with me because I'm the teacher of that class and designing it. And so it became highly productive, as opposed to my teaching a class that's unrelated to my research interests that takes a lot of time to do a good job but doesn't provide any side benefit in my research program. So it worked out very well for me. It helped boost and accelerate my research. And it worked out, I think, good for the students at the time and probably for, I think, the department, because now they get a new field being taught. And students are actively interested in it, and research is happening at MIT. So it was a very good experience moving into teaching and the faculty position at MIT.

INTERVIEWER: So you mentioned that your research topic became hot, which clearly is related to the rise of computer networks and the importance of computer networks and ultimately the internet. I was wondering if you could talk about that, especially the internet, and at what point the research you were doing sort of became of paramount importance to that.

LEIGHTON: Yeah, that's interesting. I'm a theoretician. I certainly was a full time theoretician before. And so the quality of my work was judged based on the depth of the mathematics and the perceived importance of the problem that's being solved, not based on its perceived applicability at all. I'm in a math department. I'm in a field of theoretical computer scientists. The conferences I go to are other people like me, and we're all mathematicians underneath the covers. Now, the field itself talks about large-scale networks and doing things like routing communication problems on those networks, avoiding congestion. And so it's not a stretch to say, hey, this might be relevant to practice. And so the first brush with practice I think came with the advent of companies like Thinking Machines, which is sort of an MIT spin-out nearby here, that were actually building large-scale parallel computers and starting to use the ideas that were in these theory papers that we'd developed. So a close colleague of mine, Charles Leiserson, actually spent a lot of time at Thinking Machines. I consulted there and taught courses there in the summer with him. But that started getting a brush with practice. Unfortunately, Thinking Machines went broke, and the practical side of that field sort of faded away. There never really was a impact in practice, I would say, to the work in the '80s and early '90s. Then the next brush came actually through encouragement from DARPA. DARPA was was, and probably in some sense still is, a big funder of research in computer science at the leading universities and at MIT. In fact, back in the early to mid '90s, it was probably 2/3 of the LCS research budget was DARPA. And theoreticians always had a hard time getting research money, because we're doing math, and DARPA's interested in things-- they're out there. They like research, but they want things that are going to really be applied-- the guys building systems and stuff like that. There was always encouragement in the lab for computer science for guys like me to at least look a little more practical so that you could get funded. So I'm doing work on very large-scale networks. People are waking up that the internet's an important thing. And gee, some of the stuff we're doing seems like it might be relevant. And so I did take a step a little bit to the right and start thinking about, with the encouragement and support of guys like Tim Berners-Lee, who's the father of the web, to start thinking about problems directly in the context of the internet. Using the mathematics from the large-scale network work, how would you now tackle the problem of routing around congestion in the internet? How would you solve the problem of getting a hot piece of content or piece of news to millions or billions of people in a short amount of time? And this is the kind of problem that was right up our alley in terms of expertise-- my group and the stuff we were doing. And well, boy, if we worked on that and made some progress, we might actually get funded. So we did. And we did get funded. Now, we weren't really thinking that we're going to change the world at this point. That started happening two years after the research began. The research, we're still publishing in theoretical conferences. It's still being judged based on the mathematical depth of the work. But there's this thing at MIT called the 50K contest. And my lead graduate student on this stuff, Danny Lewin, had a next-door neighbor who was a Sloan student who knew about the 50K. And they were talking, and Danny's going broke, because he's got all these student loans, and he's a theoretician. And we didn't get paid that much, especially when you're a graduate student. Kids in private school. So Preetish talked to him about taking the work in his thesis and turning it into a business plan for the 50K competition. And so then Danny talked me into engaging with them on it. And we thought it would be a good learning experience. And so we entered the 50K process, starting with the three of us and ultimately growing to 35 people. And through that experience, we really got exposed to the real world. It's hard to imagine now, but I didn't know what a VC was. I didn't know it stood for venture capitalist, and even if I did, I wouldn't know what venture capitalists did. It seems shocking today. We learned. But as part of the 50K process, we met VCs. We met industry pundits. We ended up talking to potential customers for our pretend business plan. And so we got exposed more to the real world, and we began to understand that wow, our technology really could work in practice and make a difference. And that was a first, a fundamental change. Because people who do mathematics and do theoretical computer science, that's a very rare outcome. Now, over the history of the field, there's been huge advances in practice from work on theoretical computer science. It really is a vital field to the economy and to the industry. But a lot of the work takes a long time before it's relevant, if ever. And this was sort of an eye-opening experience for us to see that, wow, we might be able to do something in the real world.

INTERVIEWER: So I know that at one point, with the work that ultimately became Akamai or on which Akamai founded, at one point you had attempted to approach various ISPs, internet service providers, and interest them in the work and had kind of gotten the brush-off. Was this before or after the 50K experience?

LEIGHTON: This is during and at the end of the 50K experience. The original idea of our plan was to take our technology and, well, in the business plan, sell it to ISPs with the idea that they could get better performance for their subscribers and lower their cost. Now, we actually went to go talk to some ISPs. We

went to Coolidge Corner to talk to HarvardNet. We talked to several of the local ones, called up UUNET down in Reston. And we quickly learned that they had no interest in what we were talking about. They said, look I can get caching software for free. I got much bigger problems to worry about. I'm going broke. And distributed computing, everybody knows that doesn't work in the real world. That's an ivory tower concept. Please go back to your ivory tower and let me get back to saving the company. They're all up in flames. They're in the process of going broke. That was not encouraging, so we modified our business plan over time. At the end of the 50K, we decided not to form a company. We were actually approached by some VCs that said, hey, look, you didn't win the contest, but we liked what you're doing. It's MIT. It's sexy. It's the internet. Let's go. Let's make a company, and in six months, we'll flip it. We're all going to go home rich. And again, showing you how naive we were, we said no. We didn't want to do that. I liked being a professor. Danny wanted to become a professor at MIT. And he was smart enough to do that. The business plan had been fleshed out. And we didn't know anything about really starting a company. The 50K thing had been as a learning experience and for fun and a challenge. We did keep thinking about it. We did have to decide about are we going to patent things or open source it? I remember having discussions with Tim and Michael Dertouzos, head of the lab, about that. As part of that, we talked about hey, can't we just get the companies to use the technology? Because we wanted it to be used. And even if we made it free, they didn't think it would work. They think they had other things for free that if they needed to go there, they could go there. And there just was no takers. And so at the end of the day, we decided that this is our chance to make a difference with technology. It doesn't come along very often in what we do. And we'd modified our business plan, changed it around, so we felt it could work, changed it to selling to people with websites-- the big websites of the world. Talked to some of them, and they started expressing interest, which was better than we'd had before with the ISPs. And so we said, the only way we're going to do this is to do it ourselves, so let's give it a try. So we spun out of MIT at the end of the summer of '98, a year after the 50K started and got offices over in One Kendall and then called up those VCs and said, hey, we could use some money. Turned out to be harder than we thought to actually get the money on terms we wanted, so we had a period of about three to four months where we were funding it ourselves with friends and with some angels, professional angels. We had friends of friends we knew to bridge us to the first round with the VCs.

INTERVIEWER: So stepping back for just one minute, what was the big idea behind what ultimately became Akamai? And why do you think there was so much resistance among those initial people, the ISPs that you approached? You mentioned sort of this ivory tower attitude that they had. But just expand on that a bit.

LEIGHTON: It's not one idea per se, but it's an approach. And the approach is mathematical and with depth in technology. And that's not the way any of those guys would approach it or even understand it. I still remember-- it seems funny in retrospect. Today I'm a professional salesman. I go out, and I give talks to customers or at keynotes at major conferences and explain the future of the internet and stuff like this. Back then, we would go talk to people. I'd get out my deep technical slides on here's the proof that consistent hashing, our brilliant new algorithm, does all these great things. And I'd start giving them a proof, mathematical proof, to the VCs. They didn't have a clue what I was talking about. out But somehow they had some belief that we were going to do something good. So it was based on deep technology. Not the deepest math ever done for sure, but in terms of this field, bringing some depth in mathematics to the field, that was different. It used distributed computing. It used algorithms. The algorithms were expressed as a function of n. n? What's n? So it's just very different than the way they would think. They'd build something for size four and then build a new one for size eight. And here we're just thinking at a whole different level. Ultimately it is that capability which made us be so successful, I think, in addition to getting really strong people who worked really hard. But having that technology, I think, made a real difference and still drives the company today. It allows us to give a lot better services than the dozens of competitors that have sprung up over the years. So I would say it's not so much one idea but a philosophy. One person I remember-- actually a well-known person in the field-- said to us years later, the only reason we were successful is because we were too naive to know that what we were trying to do was impossible. Because we were naive, and we did things out of the box. And we weren't constrained by the thinking in the industry at the time. Because we weren't even practical people. Here we are now building systems without a clue how you're supposed to do it. That means we made a lot of mistakes, but we also did things differently, because we were mathematicians building a large-scale system. And so we came at it from a very different angle, and that helped in some ways. Today, of course, we've evolved to the point where we have the world's best systems developers working with the mathematicians to develop our systems. You need both to really do it right. So it was sort of a philosophy, almost a naivete that we did things differently. We had a very open mind about how to approach the problems. It used things like distributed computing, which really weren't used and practiced so much back then. And we didn't know even at what level to explain things to the ISPs. Me going in and giving some proof to the guy at the ISP, I laugh at that now. No wonder they wouldn't be interested. It was what we were doing.

INTERVIEWER: I also wanted to just ask a bit more about the 50K experience. I guess first of all, for people who might not know what the 50K is, maybe just provide a little bit of context. But also you mentioned you didn't win, and yet it was also a valuable experience. Just tell me a bit more about that.

LEIGHTON: Yeah, the 50K contest, it's now called the 100K because the prize money has been increased. It's run by students in the Sloan School. And you submit a business plan. Actually there's several rounds. The first round is more of an elevator pitch. It's a one-page thing. But ultimately, as you go towards the later rounds, you flesh out a business plan and submit that. And they pick the ones they think are going to be the most successful, most likely to make money. And they use the money to fund the company. Now, in our case, we had no intention at that time of forming a company. It's a pretend exercise. And we were a bunch of folks-- Danny Lewin in particular-- that when you enter a contest, you like to win. So we got books out of the library, how to write a business plan. We didn't let our lack of experience hold us back. And we competed hard. And when we got to the final round, we saw the other finalists, and we just saw how much better they were than we were. They were very professional in their presentations, just a whole different level or two levels beyond where we were. And that was a great wake-up call, because we realized, wow, we don't know how to do it the way they do it, but we know we got to get to that level if we're ever going to be serious about it. So a slap in the face like that was good for us. At the time, we decided not to form a company. But when we changed our minds later in the summer and did start the company, knowing what we were missing was very important. And knowing what we weren't good at yet was important. Because then we would either get better at it or go get people who were really good at it. Now, in the case of the ultimate leadership of the company, both Danny and I decided that we weren't going to be the CEO. I told Danny, I'm the professor. He's the student. I told him I'd work for him if he wanted to be the CEO. I had tremendous respect for his capabilities. Tremendous leadership. Tremendous smarts. Driven guy. But he didn't want to be CEO either, because he was smart enough to recognize that he wanted to go get somebody really, really good. And we did. We got two people who are really, really good. We got Paul Sagan, who started Road Runner, and then George Conrades, who was number two at IBM, had gone to BBN. Bunch of academics there. Converted them into a real company. Sold it to Genuity very successfully. And now is an entrepreneur in residence at a local VC. So because of that experience, I think helped us understand where we needed other stuff, other people, or to improve ourselves. And we went out and got the best.

INTERVIEWER: So about a year after the 50k, you decided, okay, we're going to dive in and form a company. How did you manage to attract those kinds of people to something that was such an early startup, something that was the sort of getting bootstrapped? That would clearly seem to be a very early indicator of success. I'm just curious about how you did bootstrap it.

LEIGHTON: It was MIT. It was the internet. It was sexy. It was the bubble. We had a lot of things in our favor. We met some VCs through the 50K. We knew some people to start calling. We did research on who else to call. So the timing, the environment was great for that. Now, we also had really smart people, not

in the business necessarily, but at algorithms and computer science. And I think the VCs sensed that. I think they also sensed we were pretty clueless about business. But that's their job is to help people talented at something get the help on the business side they may need. And I think they sensed that we were motivated and committed. We wanted to have the technology be used in practice. Once we made the decision to do it, we wanted to make it be successful. We wanted it to work. And I think that helped a lot. Now, Battery Ventures, Todd Dagres was the lead for us there. He became convinced that it was a good investment for him to be engaged in. We had a second VC as his partner in the first round. And the very last minute, as the funds are supposed to be transferred-- we'd had the handshake, the signed term sheet, the deal all worked out, all ready for the final signature and the $4 million to get wired. That was happening at the Monday morning. On Sunday night, I get a call from the managing partner of the firm letting me know he's pulling out, because he just didn't think it was going to work. And that was devastating for us, because we'd already said no to all the other consortia that we'd negotiated with. And we were scared to death that that could put Battery in the driver's seat to really screw us, because we really needed the money at that point. And to their credit, Todd said, we'll go through with our share of the deal, same terms, and we'll help you find somebody to fill it out. Very important. You hear all these bad stories about VCs. That was great. So they did help us, and we went and got Polaris to fill out the round, because George Conrades was there. And we made this list of people we'd like for CEO. He was the top of the list, of your fantasy list. And he was there. And we said, okay, look we'll take Polaris if you put George on our board. And then we got him on our board. And then we seduced him into being the CEO.

INTERVIEWER: This is probably a good time for me to ask sort of the larger question about this mind-bending transition from being a professor to being an entrepreneur, to sort of be dealing with all of these things-- VC funding, and first round, second round, finding a CEO. What did that feel like?

Level 3 Communications, Inc.

Traded as NYSE: LVLT

Industry Telecom

Fate : Acquired by CenturyLink

Founded 1985

Headquarters Broomfield, Colorado, United States

Key people

James O. Ellis Jr. (Chairman)

Jeff Storey (CEO)

Sunit Patel (CFO)

Products

Mobile telephony, Internet services, Content delivery

Revenue US$ 8.3 billion (2015)[1]

Operating income US$ 1.3 billion (2015)[1]

Net income US$3.4 billion (2015)[1]

Total assets US$24.1 billion (2015)[2]

Total equity US$10.1 billion (2015)[3]

Number of employees 13,500

Parent CenturyLink

Level 3 Communications was an American multinational telecommunications and Internet service provider company headquartered in Broomfield, Colorado. It ultimately became a part of CenturyLink, where Level 3 President and CEO Jeff Storey was installed as Chief Operating Officer, becoming CEO of CenturyLink one year later in a prearranged succession plan.

Level 3 operated a Tier 1 network.[4] The company provided core transport, IP, voice, video, and content delivery for medium-to-large Internet carriers in North America, Latin America, Europe, and selected cities in Asia.[5] Level 3 was also the largest competitive local exchange carrier (CLEC) and the 3rd

largest provider of fiber-optic internet access (based on coverage) in the United States.

On October 31, 2016, CenturyLink announced an agreement to acquire Level 3 Communications in a cash and stock transaction.[6] Level 3 became part of CenturyLink on November 1, 2017.

History

1985 to 2000

In 1985, **Kiewit Corporation** created a subsidiary named **Kiewit Diversified Group** to manage the corporation's business that was not related to construction. The division was spun off as a separate entity and changed its name to Level 3 Communications in 1998 to signify an increased focus on communication services. That same year saw it make an IPO on NASDAQ. According to Level3's own history, it continued to build its telecommunications network after going public.

2001 to 2010

According to Level 3's own history, in 2003, the company acquired **Genuity**, and, between 2005 and 2007, it purchased several other companies including former rivals WilTel Communications, Broadwing Corporation, Looking Glass Networks, Progress Telecom, and Telcove (formerly Adelphia Business Solutions).[7] In 2004, Level 3 acquired ICG Communications' wholesale dial-up business for $35 million. Then, in 2006, Level 3 purchased the rest of ICG Communications for $163 million, taking over ICG's fiber network and nationwide Points of Presence (PoPs). It then integrated these companies through 2010.

2010 to present

On April 11, 2011, Level 3 announced a tender offer had been made to acquire fellow Tier 1 provider Global Crossing[8] in an all-stock transaction,[9] which was approved by shareholders on August 5,[10] and completed on October 4, 2011. On October 20, 2011, Level 3 Communications reduced its total shares and transferred its stock listing from NASDAQ to the larger New York Stock Exchange.[11]

On May 14, 2012, Level 3 was contracted by European content provider Voxility to provide 250 Gbit/s or more to Voxility's three main data centers in North America and Europe.[12] On May 7, 2012, Level 3 was contracted by the U.S. Department of Defense's Defense Information Systems Agency to provide fiber-cable operations and maintenance, and IP-based infrastructure under a ten-year, indefinite contract with a maximum value of approximately $411 million.[13]

On June 16, 2014, Level 3 acquired TW Telecom, a business Internet connection provider, for about $5.7 billion.[14]

In July 2015, Level 3 acquired Black Lotus, a provider of protection against distributed denial of service (DDoS).[15]

On October 31, 2016, [**CenturyLink, Incorporated**, known as of Sep 2020 as **Lumen Technologies, Incorporated**,] announced its intent to acquire Level 3 in a deal valued at around $34 billion.

On October 3, 2017, the deal was approved by the United States Department of Justice on condition of selling some of Level 3's telecom holdings in three states.[17] The deal officially closed and Level 3 became part of CenturyLink on November 1, 2017.

On November 1, 2017, Level 3 Communications officially merged with [CenturyLink, Incorporated , known as of Sep 2020 as Lumen Technologies, Incorporated]. As part of the merger, work was required to divest of 24 individual fiber optic lines spanning 30 city pairs as required by the US Department of Justice. Additionally, Level 3 was required to divest of metro Ethernet markets in Boise, Tucson, and Albuquerque to satisfy antitrust requirements. The company complied with the divestiture of those assets.

Operations

Network

Level 3 Communications satellite dish on one of its two ground stations located in Boise, Idaho

Level 3 Communications operated a large network Internet, with infrastructure in 46 states in the continental United States,[20][21] South America, Western Europe,[4][22] and some cities in Asia. It uses transatlantic cables,[23] including "Yellow" /AC-2 (on which it owned two of the four fiber pairs after Viatel's 2001 bankruptcy).[24] Level 3 Communications has also purchased 300 Gbit/s of capacity on the Apollo (cable system).[25]

At the time of acquisition by CenturyLink, it was owner of AS1[26] (following the acquisition of Genuity, from BBN Technologies), but it used AS3356 for operations. AS3356 as of 2007 consistently had one of the highest ranked connectivity degrees on the Internet.[27][28] It also operated the former Global Crossing network (AS3549) following the company acquisition in 2011.

Level 3 Communications delivered Netflix and Apple music and video content over the Internet.[29] The company ran a content delivery network which it acquired from Savvis in 2006.[30]

In 2006, Level 3 Communications announced with Internet2, an academic network, that they would deploy a next generation nationwide research network.[31]

Sales organization

Level 3 distributed and sold its services through a mix of six independent sales channels: large enterprise, wholesale, federal, content and media, midmarket, and indirect. All six sales channels reported to the president of sales Andrew Crouch.[32] The top performing Level 3 indirect sales agencies in 2010 included Intelisys, Microcorp, CDW/AVANT Communications, PlanetOne, Advantage Communications Group, Telarus, and Presidio.[33]

Comcast dispute

On November 11, 2010 a dispute arose between Level 3 and Comcast, when Level 3 announced that they were "selected to serve as a primary content delivery network (CDN) provider for Netflix, Inc. to support the company's streaming functionality."[34] Apparently, as a result of this distribution agreement, Comcast sought to renegotiate the peering agreement with Level 3 and sought a recurring fee for carrying the increased Level 3 internet traffic to and from Comcast broadband customers. Claims[35] and counter-claims[36] were made as the two companies sought to renegotiate the contract. In December 2010, the New America Foundation submitted information concerning the dispute to the FCC.[37]

December 2013, the New America Foundation submitted information concerning the dispute to the FCC.[37]

On July 16, 2013, Level 3 Communications and Comcast seemingly ended their three-year dispute by issuing a statement that "Level 3 and Comcast have resolved their prior interconnect dispute on mutually satisfactory terms. Details will not be released."[38] On May 21, 2015, Level 3 and Comcast announced a new multi-year bilateral agreement to "enhance their existing network capacity while extending their mutual interconnection agreements, ensuring that both maintain ample capacity to exchange Internet traffic between their networks."[39][40]

Other disputes

In July 2013, the NSA was accused of wiretapping large parts of data on the German Internet Exchange Point DE-CIX which was denied by Level 3,[41] and a few months later, was accused of tapping connections between Google and Yahoo data centers.[42]

STATE/LOCAL 7E

Peter Kiewit Sons firm announces reorganization

OMAHA (AP) — Officials at the Peter Kiewit Sons' Inc. construction company have announced a corporate reorganization that creates two classes of stock and combines businesses.

Officials said the reorganization created Class C stock, which tracks the company's construction and mining businesses. Another class — Class D — pertains to the company's other businesses, including telecommunications and electrical energy.

Walter Scott Jr., Kiewit's chairman, presented the new structure to stockholders at the annual meeting Friday in Omaha. Stockholders of the privately held firm approved the reorganization in December, Kiewit officials said.

Under the reorganization, Scott remains president and chairman of Peter Kiewit Sons Inc. and also will serve as president of Kiewit's Diversified Group, which includes the telecommunications and energy businesses, the company said.

The company's construction and mining businesses are combined under the new structure.

Charles H. Campbell, a Kiewit executive vice president and former president of the construction group under the old structure, was promoted to vice chairman of the parent firm. He also was named chairman of the Construction and Mining Group, the company said.

Kenneth E. Stinson, president of the mining group under the old structure, was named president of the construction and mining segment.

James Q. Crowe, who was division manager in the old construction group, will serve as president of Kiewit's Telecommunications Group, the company said.

Kiewit had construction and mining revenues of about $2 billion in 1991, company spokesman Brad Chapman said Friday. He declined to say what the firm's total revenue was.

The company had $5.1 billion in revenue in 1990, according to Fortune magazine.

Kiewit was under contract to build more than 700 projects in 1991. The company said it shipped about 17 million tons of coal.

Kiewit operates construction offices through the United States and Canada. The company builds major projects in the power, commercial building and telecommunications industries.

The company has 2,900 salaried, full-time employees and employs 20,000 to 25,000 independent craftsmen each year, Chapman said.

1998 (Jan 20) - "Kiewit Diversified" changed it's name to Level 3

Full page : [HN01CL][GDrive]

Fremont Tribune (Fremont, Nebraska) · 20 Jan 1998, Tue · Page 12

Kiewit Diversified plans name change, move to Denver

OMAHA (AP) — Kiewit Diversified Group has chosen Denver as the site of a new Internet-based company expected to create up to 3,000 jobs.

The company made the announcement Monday. It said it would not move until it receives word from the Internal Revenue Service on whether the company's split from Peter Kiewit Sons can be tax-free.

Kiewit Diversified is a subsidiary of Peter Kiewit Sons, an Omaha-based construction and mining company.

The company announced in December it would start the Internet-related business elsewhere because of the difficulty of attracting computer nerds to Omaha.

The IRS decision is expected before the end of June. The relocation will affect 30 to 40 Kiewit Diversified executives. No other Kiewit operation will be affected.

Kiewit Diversified also said it is changing its name to Level 3 Communications to better reflect the new venture.

Level 3 Communications will focus on building a nationwide, Internet-based network to compete with local and long distance telephone systems, the company said. Long-range plans include international competition.

Areas under consideration for the new headquarters were Dallas, northern Virginia and the Silicon Valley in California.

[HN01CM][GDrive]

1998 (Jan 21) - "Peter Kiewit Sons to Build National Fiber Optic Network"

By Seth Schiesel / Source : [HN00ZF][GDrive]

Adding to the growing list of companies that are building new national communications networks, Peter Kiewit Sons Inc. has said that it intends to spend up to $3 billion over the next three years to build a 20,000-mile web of fiber optic cable.

The system, which the company wants to complete by 2001, would be the first national fiber optic network based on Internet technology rather than on standard telephone technology. If the Internet technology works as predicted, it could allow Kiewit to charge prices for voice and data communications much lower than those of its competitors while maintaining healthy profit margins.

Kiewit plans to sell access to its network only to business customers. Most of those would be small and medium-sized companies, but some could be upstart long-distance carriers that would resell time on the Kiewit network to consumers.

On Monday, the Kiewit subsidiary that intends to build the network, [**Kiewit Diversified Group**], announced that it had changed its name to **Level 3 Communications Inc. Level 3 is led by a team of executives who used to run the** [**MFS Communications Company, Incorporated**], the alternate local telephone carrier acquired in 1996 by Worldcom Inc. for $14 billion.

The move by Kiewit, a private company based in Omaha that has its primary operations in construction and mining, brings to four the number of companies building new national communications networks. Kiewit joins IXC Communications, the Williams Companies and the Qwest Communications subsidiary of the Anschutz Corporation. Established long-distance carriers like the AT&T Corporation also spend billions each year upgrading their systems.

But Level 3's network would differ from the others in its reliance on Internet Protocol, or I.P., technology. I.P. can allow networks to be used more efficiently but can also be less reliable than traditional networks. Traditional networks generally allow voice and data messages to be transmitted in one continuous chunk. I.P. networks break messages into small packets that are each sent independently to their destination.

"I.P. is ready for prime time," said [**James Quell Crowe (born 1949)**], Level 3's chief executive, who was MFS's chairman. He said, however: "With today's technology, I.P. is fine for anything that's not timing-sensitive, like data or fax. Anything that's timing-sensitive, primarily voice and video, isn't handled very well."

But Mr. Crowe said that advances in the technology over the next few years would allow Level 3 to offer voice quality equal to that of more traditional systems.

Mr. Crowe said that Level 3 had about $2 billion in cash but that it was confident it could raise the remainder necessary to complete its network.

2002 (Nov 27) - NetworkWorld - Level 3 to buy bankrupt Genuity's assets

Stephen LawsonBy Stephen Lawson ; See [HP004I][GDrive]

This article is also located at **Verizon Communications Incorporated** and **Genuity Incorporated (2000)**

Internet backbone provider [**Level 3 Communications, Incorporated**] has agreed to acquire the bulk of the assets of network provider **Genuity** [(Genuity Incorporated (2000))], which has filed for bankruptcy, the companies announced Wednesday.

Level 3 will pay as much as $242 million in cash and assume a significant portion of **Genuity's** long-term operating agreements, according to a statement from the companies. The deal must be approved by regulatory agencies and a bankruptcy court and is expected to close in the first quarter of 2003.

Also Wednesday, **Genuity** [(Genuity Incorporated (2000))] filed voluntary petitions for reorganization under Chapter 11 of the U.S. bankruptcy code, the statement said. The cash on Genuity's balance sheet, together with Level 3's cash payment, will be distributed to creditors of Genuity.

Based in Woburn, Mass., **Genuity** [(Genuity Incorporated (2000))] was spun out of U.S. telecommunications carrier [Verizon Communications Incorporated] according to the terms of the merger of Bell Atlantic and [GTE Corporation] that created Verizon in 2000. More recently, the company has been suffering financially amid a glut of capacity on backbone networks. In May, Genuity announced that it would cut as much as 30 percent of its workforce, or 1,200 jobs.

[**Level 3 Communications, Incorporated**], in Broomfield, Colorado, will acquire Genuity's network transport business as well as its dedicated and dial-up Internet access operations. It also will take over Genuity's managed services business, which it will combine with its iStructure subsidiary but continue to operate under the Genuity brand.

Genuity's biggest customers are Verizon and AOL, according to the statement. Verizon has executed a new multi-year contract to buy wholesale dial-up, transport and other services from Level 3, which should take effect when the acquisition closes.

2002 (Nov 27) - "Level 3 to acquire Genuity assets and operations for $242 million"

Source - LightWaveOnline - [HW005H][GDrive]

This article is also located at [**Verizon Communications Incorporated**]

[**Level 3 Communications, Incorporated**] and **Genuity Inc.** [(Genuity Incorporated (2000))] announced today that they have signed a definitive agreement under which Level 3 will acquire substantially all of the assets of the Massachusetts-based communications company.

[**Level 3 Communications, Incorporated**] will pay up to $242 million in cash and assume a significant portion of existing long-term operating agreements to acquire Genuity's assets and operations. To facilitate the transaction, **Genuity** [(Genuity Incorporated (2000))] today is filing voluntary petitions for reorganization under Chapter 11 of the Bankruptcy Code. Level 3's cash consideration at closing could be reduced subject to certain material adjustments.

Closing is expected to occur during the first quarter of 2003. The transaction is subject to approval by the bankruptcy court and certain government regulatory agencies.

"This transaction represents the best outcome for the key constituencies of both Genuity and Level 3," contends Paul R. Gudonis, chairman and chief executive officer of Genuity. "Both companies, as well as Genuity's largest customers and creditors, have signed agreements supporting the transaction."

"There is a unique and compelling fit between Genuity and Level 3," adds [James Quell Crowe (born 1949)], Level 3's chief executive officer. "The transaction combines the assets and operations of Genuity, the company that helped invent the Internet, with Level 3, the company that built the first network fully optimized for Internet Protocol-based communications. Both companies are experienced providers of optical and IP-based services, and both are Tier 1 Internet backbone providers with industry-leading quality of service. Genuity's transport and dedicated and dial-up Internet access business--more than 80 percent of revenue--is complementary to Level 3's transport, managed modem and IP services business."

Based in Woburn, MA, **Genuity** [(Genuity Incorporated (2000))] operates an international IP network. The company provides dial-up and dedicated Internet access, transport, managed security and VPN, hosting and other services to communications companies, enterprises and government agencies. Its largest customers are Verizon Communications and America Online, which accounted for greater than 60 percent of its $223 million in revenue for the third quarter of 2002.

All but one of Genuity's banks have signed an agreement in support of the transaction. Verizon has executed a new multi-year contract to purchase wholesale dial-up, IP, transport and other services from Level 3, to take effect when the transaction closes. America Online has signed an agreement consenting to the transaction that contemplates [**Level 3 Communications, Incorporated**] acquiring America Online's network services agreement with Genuity. In addition, Allegiance Telecom Inc., Genuity's largest network supplier, supports the transaction.

As part of this transaction, Level 3 is also acquiring Genuity's managed services business and its associated enterprise customers and product set. "We recognize the importance of these customers and are committed to ensuring they receive the highest quality service without disruption," asserts Kevin O'Hara, president and chief operating officer of Level 3. "As a result, we plan to combine these operations with those of our (i)Structure subsidiary in order to focus on the needs of those customers. That new managed services operating company will do business under the name 'Genuity,' a recognized leader in that market." [...]

2003 (Aug 19) - CenturyLink corporate news - Level 3 to Sell Midwest Fiber Optic Network Acquired in Genuity Transaction

See [HC004L][GDrive]

This article is also located at [**Verizon Communications Incorporated**]

BROOMFIELD, Colo., Aug. 19 /PRNewswire-FirstCall/ -- [**Level 3 Communications, Incorporated**] announced today that it has signed a definitive agreement to sell the **Midwest Fiber Optic Network (MFON)**, a regional communications system it acquired through its recent transaction with **Genuity** [(Genuity Incorporated (2000))].

CenturyTel (NYSE: CTL) will purchase the stand-alone system, which serves as a regional backbone for a number of carriers, including CenturyTel itself, in Arkansas, Missouri and Illinois. The purchase price is approximately $17 million in cash, subject to adjustments including date of closure and system revenue at time of close. Closing is subject to regulatory approvals and customary conditions.

"This is a non-core asset for Level 3," said Sunit Patel, Level 3's chief financial officer. "While MFON currently generates approximately $1.5 million a month in revenue, the geography and architecture of the system do not offer us a practical or cost-effective way to integrate its operations into the Level 3 network. As such, we believe it makes sense to sell this business and continue to focus on the integration of the core assets, customers and traffic from the Genuity transaction."

Closing is expected to occur by the end of the fourth quarter of 2003.

Daniels & Associates, the Denver-based media and telecommunications mergers and acquisitions specialist, served as financial advisor to Level 3 on this transaction.

- **About Level 3 Communications :** Level 3 (Nasdaq: LVLT) is an international communications and information services company. The company operates one of the largest Internet backbones in the world, is one of the largest providers of wholesale dial-up service to ISPs in North America and is the primary provider of Internet connectivity for millions of broadband subscribers, through its cable and DSL partners. The company offers a wide range of communications services over its 22,500-mile broadband fiber optic network including Internet Protocol (IP) services, broadband transport, colocation services, and patented Softswitch-based managed modem and voice services. Its Web address is www.Level3.com. The company offers information services through its subsidiaries, (i)Structure and Software Spectrum. For additional information, visit their respective web sites at www.softwarespectrum.com, and www.i-structure.com.
- **About CenturyTel :** CenturyTel, Inc. provides communications services including local, long distance, Internet access and data services to more than 3 million customers in 22 states. The company, headquartered in Monroe, Louisiana, is publicly traded on the New York Stock Exchange under the symbol CTL, and is included in the S&P 500 Index. CenturyTel is the 8th largest local exchange telephone company, based on access lines, in the United States. Visit CenturyTel at www.centurytel.com.

2010 (Oct 04) - Business Wire : "President Obama Names Level 3 CEO James Crowe as Chairman of National Security Telecommunications Advisory Committee"

See [HW005D][GDrive] / October 04, 2010 07:46 PM Eastern Daylight Time

[**Level 3 Communications, Incorporated**] today welcomed President Obama's announcement of his intent to appoint James Q. Crowe, the company's chief executive officer, to the position of Chair of the National Security Telecommunications Advisory Committee (NSTAC).

"The public/private partnership of the NSTAC has resulted in unique contributions to critical infrastructure protection, information sharing, network convergence, security and communications infrastructure reliability across the nation."

As chairman, Crowe will preside over a 30-member committee that comprises industry executives from major network service providers, IT, finance and aerospace companies. The NSTAC provides critical industry-based analyses and advice to the President on policy and technical issues regarding national security and emergency preparedness communications. The committee also develops recommendations to the President to assure vital telecommunications links through any event or crisis.

"I am honored by the opportunity to chair this important committee," said Crowe. "The public/private partnership of the NSTAC has resulted in unique contributions to critical infrastructure protection, information sharing, network convergence, security and communications infrastructure reliability across the nation." [...]

2013 (May 09) - Omaha World Herald - "Crowe, who built Level 3 Communications from ground floor, to retire"

By Barbara Soderlin WORLD-HERALD STAFF WRITER / Source : [HN01CR][GDrive]

[James Quell Crowe (born 1949)], who led the development of **Level 3 Communications** from its Omaha origins, announced Thursday he plans to retire by the end of 2013 from his position as the Broomfield, Colo., firm's chief executive officer.

The board of directors, led by chairman [Walter Scott Jr. (born 1931)], has formed a committee to select a new CEO. Crowe will remain on the board.

Crowe led [MFS Communications Company, Incorporated] in Omaha when it was a subsidiary of Peter Kiewit Sons' Inc. under Scott and after it was spun off in 1995. It was sold in 1996, and Crowe returned to Kiewit to head the [Kiewit Diversified Group], which was founded in 1985 to hold Kiewit's nonconstruction assets.

A year later, he announced that Diversified Group would move its headquarters out of Omaha and start an Internet-related telecommunications business in a city where it would have an easier time attracting high-tech workers. It was discouraging news to the Omaha business community at a time when the Peter Kiewit Institute was in its infancy.

In 1998, [Kiewit Diversified Group] changed its name to **Level 3 Communications Inc.** and started trading on the NASDAQ exchange, drawing heavy investment from the Omaha area.

Today the firm provides data, Internet, voice, video, security, IT and managed services. It has service in more than 70 countries and more than 100,000 “route miles” of fiber optic cable.

“Level 3,” Crowe said, “is extraordinarily well-positioned to benefit from the worldwide explosion of voice, data and video carried over the Internet.”

In February, it reported year-end revenue of $6.38 billion, up from $6.32 billion in 2011. Level 3 in 2012 had a net loss of $422 million, compared with losses of $875 million the year before.

[Walter Scott Jr. (born 1931)] thanked Crowe for his leadership and for all that he has done to build Level 3. “It is no exaggeration to say that, without Jim, there would be no Level 3.”

CompaniesHistory : Level 3 Communications

Source from CompaniesHistory : [HW003Q][GDrive]

Video : https://www.youtube.com/watch?v=1yaAAwQ83Vs#action=share : Level 3 Communications - Introduction - All about Level 3, the leading network behind the internet :

•Sep 8, 2010 : **Level3Communication :** Level 3 is the leading IP Upstream carrier transferring terabytes per second around the globe. Find out how Level 3 enables the internet by providing bits and bytes on its fiber optic network around the world.

Level 3 Communications, Inc. provides a range of integrated communications services, non-switched and local-access telecommunications services. It provides IP-based communications services to enterprise, content, government and wholesale customers. The company delivers integrated IP solutions, including converged, data, voice, video and managed solutions to help enable customer's growth and efficiency. It operates through the two segments include: Level 3 and Global Crossing. The Level 3 segment offers services, include core network to transport, infrastructure, data, local and enterprise voice services, wholesale voice to domestic voice termination, international voice termination and toll free services and other communications services. The Global Crossing segment offers services include invest and grow through other carriers, sales agents and system integrators to transport, infrastructure, IP and data, voice and collaboration services to carrier and enterprise customers, Voice Services and Other services. Its content distribution products and services comprise content delivery network, media delivery services and fiber optic and satellite video transport services. Level 3 Communications was founded in 1985 and is headquartered in Broomfield, CO."

History - Stronger Connections around the Globe

From its beginning, Level 3 Communications was founded on the principles of the Silicon Economics℠ cycle: create a global telecommunications network with the scale to reduce unit costs, stimulate demand with these lower costs, support that demand by scaling even more. Level 3 created a network that serves as a foundation for the communications services of the 21st century by providing, among other things, information transmission over a fiber optic network and media delivery over a content delivery network. And we've grown to support the end-to-end communications services that businesses and carriers rely on.

Level 3 was originally founded in 1985 as Kiewit Diversified Group Inc. (KDG), a wholly-owned subsidiary of Peter Kiewit Sons', Inc. (PKS). Peter Kiewit Sons', Inc. is a 114-year-old construction, mining, information services and communications company headquartered in Omaha, Neb. KDG was originally created to hold PKS' non-construction business assets.

In early 1998, KDG announced it was changing its name to Level 3 Communications, Inc., after substantially increasing the emphasis it placed on and the resources devoted to its communications and information services business. On April 1, 1998, Level 3 common stock started trading on the NASDAQ Stock Market under the symbol LVLT.

During 1998, Level 3 raised $14 billion and was called the "best funded start-up in history." The company constructed 19,600 route miles, and built the world's first continuously upgradeable network fully optimized for internet protocol (IP). Over the next few years, explosive demand for bandwidth fueled growth in sales. By the end of 2000, Level 3 provided service to 2,700 customers.

Level 3 continued investments in infrastructure to become a world-class communications provider, and won the trust of the world's most sophisticated communications companies. In addition to ongoing construction, the company expanded its assets with the February 2003 acquisition of Genuity. Over the next few years, and through a major industry downturn, Level 3 pursued a strategy that focused on both the balance sheet and investing for the inevitable industry rebound. Level 3 won the confidence of investors, as the company raised more money than all other NexGen carriers combined; and also of customers, who made Level 3 one of the world's top three Internet traffic carriers.

Beginning with the late-2005 acquisition of WilTel, Level 3 has established itself as a natural industry consolidator. During 2006, the company went on to acquire Progress Telecom, ICG, TelCove and Looking Glass Networks. In 2007, Level 3 acquired Broadwing, the Content Delivery Network (CDN) services business of SAVVIS, Inc. and Servecast.

In the fall of 2011, Level 3 and Global Crossing joined forces. The new integrated network united Level 3's broad, deep U.S. and European footprint with Global Crossing's extensive international, intercity network. Continuing to operate under the name of Level 3, this new kind of company featured more than 500 global markets in North America, EMEA, Latin America and Asia, as well as a total of ~100,000 route miles."

1998 (April 6) - Wall Street Journal - "Level 3 Agrees to Acquire XCOM In $165 Million Bid for Business"

Source - [HN01H1][GDrive]

Level 3 Communications Inc., whose efforts to build a national Internet-based communications network have left it under close scrutiny, said Monday that it agreed to acquire XCOM Technologies Inc., a provider of local-phone services and communications software, for about $165 million worth of stock.

Level 3, of Omaha, Neb., will exchange about 2.6 million shares to acquire XCOM, of Cambridge, Mass. Level 3 expects to close the deal during the second quarter.

The deal comes less than a week after Level 3 made an unusual debut on the Nasdaq National Market. The firm was a division of Peter Kiewit Sons Inc., a diversified holding company, and its stock previously traded on the OTC bulletin board as Class D Kiewit stock. Level 3 completed its split from Kiewit last week.

"This is an exciting and important merger for both companies," said James Q. Crowe, Level 3's president and chief executive officer, noting that XCOM holds the rights to technology which provides key components of the "bridge" necessary to fully interconnect the public switched telephone network with new networks based on the Internet Protocol, or IP -- such as that being built by Level 3.

"This bridge will allow Level 3 to offer a broad range of communications services, including voice and fax services, to customers at lower cost and, over time, with new features and enhancements," Mr. Crowe said. "Moreover, customers will be able to enjoy these benefits using their existing telephone equipment and without changing dialing patterns or adding additional devices."

David F. Callan, XCOM's president and chief executive, said both Level 3 and XCOM "are aggressively embracing and helping to shape the new world of IP-based technology and communications."

"Our cultures and views are virtually the same," he said. "Both companies' executives come from entrepreneurial backgrounds with successful track records in starting up and growing companies to very substantial size and success in their markets."

Level 3 doesn't have any customers, and it is still negotiating land rights to build its network. Yet, with some 147 million common shares outstanding, the company ended the first day of Nasdaq trading with a market capitalization of $10.91 billion.

The company, which is run by former managers of telecommunications trailblazer [**MFS Communications Company, Incorporated**], is armed with $3 billion in funding and has charted plans to build the first global system of Internet-based local and long-distance networks, a system which it sees as offering it the chance to challenge mature phone companies in major markets. Mr. Crowe built MFS and sold it to WorldCom Inc. for $14 billion two years ago.

Level 3 plans to employ the latest in fiber optics and packet data switches and routers to move voice and data traffic from users of the Internet. The plan, using IP technology, is a highly efficient, more powerful data-transmission alternative to traditional phone networks, which use slower circuit switches and are engineered primarily to handle phone calls.

Transmission via data packets, in which great stores of information are sent in electronic envelopes in a digital format over a high-speed data network, is far less costly than sending it along traditional phone lines and through switches, which use up far more transmission capacity to transmit calls and data and are far more expensive to operate.

Despite the buzz Level 3's plans have generated, doubters note that the company faces a great deal of competition, both from other network builders and phone giants eyeing similar opportunities.

Last month, Level 3 announced a deal to lease capacity on Frontier Corp.'s fiber-optic network for up to five years in an agreement valued at around $165 million. Frontier is helping to build a $475 million fiber-optic network that is set to be completed by the end of this year.

In trading on the Nasdaq Stock Market Monday, shares of Level 3 slipped $1 to close at $61.50.

Rank

Captain

Daniel Mark Lewin (Hebrew: דניאל "דני" מארק לוין; May 14, 1970 – September 11, 2001), sometimes spelled **Levin**, was an American–Israeli mathematician and entrepreneur who co-founded internet company [**Akamai Technologies, Incorporated**]. A passenger on board American Airlines Flight 11, it is believed that Lewin was stabbed by one of the hijackers of that flight, and was the first person murdered during the course of the attacks.[1][2][3]

Early life[edit]

Lewin was born May 14, 1970 in Denver, Colorado, and moved to Israel with his parents at age 14 and was raised in Israel.[4]

Career[edit]

Lewin served for four years in the Israel Defense Forces (IDF) as an officer in Sayeret Matkal, one of the IDF's special forces units.[4] Lewin earned the rank of captain.[2]

He attended the Technion – Israel Institute of Technology in Haifa while simultaneously working at IBM's research laboratory in the city.[5] While at IBM, he was responsible for developing the Genesys system,[5] a processor verification tool that is used widely within IBM and in other companies such as Advanced Micro Devices and SGS-Thomson.[5]

Upon receiving a Bachelor of Arts and a Bachelor of Science, summa cum laude, in 1995,[5] he traveled to Cambridge, Massachusetts, to begin graduate studies toward a Ph.D at the Massachusetts Institute of Technology (MIT) in 1996. While there, he and his advisor, Professor [**Frank Thomson Leighton (born 1956)**], came up with consistent hashing, an innovative algorithm for optimizing Internet traffic.[6] These algorithms became the basis for [**Akamai Technologies, Incorporated**], which the two founded in 1998.[5] Lewin served as the company's chief technology officer and a board member, and achieved great wealth during the height of the Internet boom.[7]

Lewin's name is located on Panel N-75 of the National September 11 Memorial's North Pool, along with those of other passengers of Flight 11.

Death and legacy[edit]

Lewin was reportedly stabbed aboard American Airlines Flight 11 as it was hijacked during the September 11 attacks. A 2001 FAA memo suggests he may have been stabbed by Satam al-Suqami after attempting to foil the hijacking.[8][9] According to the FAA, Lewin was seated in business class in seat 9B, close to hijackers Mohamed Atta, Abdulaziz al-Omari and al-Suqami. It was first reported that he had been shot by al-Suqami, although this assertion was later changed to a stabbing. According to the 9/11 Commission, Lewin was stabbed by one of the hijackers, probably Satam al-Suqami, who was seated directly behind him. The commission speculates that this may have occurred during an attempt by Lewin to confront one of the hijackers in front of him, not knowing that al-Suqami was sitting just behind him.[10] Lewin was identified as the first victim of the September 11 attacks.[2][3][11]

Lewin, who was 31, was survived by his wife Anne and his two sons, Eitan and Itamar, who were aged five and eight at the time of the September 2001 attacks.[4][5][12]

After his death, the intersection of Main and Vassar Streets in Cambridge, Massachusetts, was renamed Danny Lewin Square in his honor.[12] The award given to the best student-authored paper at the ACM Symposium on Theory of Computing (STOC) was also named the Danny Lewin Best Student Paper Award, in his honor.[6] In 2011, on the tenth anniversary of his death, Lewin's contributions to the Internet were memorialized by friends and colleagues.[13][14]

At the National 9/11 Memorial, Lewin is memorialized at the North Pool, on Panel N-75.[15]

Lewin is the subject of the 2013 biography *No Better Time: The Brief, Remarkable Life of Danny Lewin, the Genius Who Transformed the Internet* by Molly Knight Raskin.

Awards[edit]

- 1995 – Technion named him the year's Outstanding Student in Computer Engineering.
- 1998 – Morris Joseph Levin Award for Best Masterworks Thesis Presentation at MIT.

Key pasage - His father Charles Lewin actually had an Altair

See **MITS Inc. Altair 8800** , made by **Micro Instrumentation and Telemetry Systems (MITS) Incorporated** .

FROM A YOUNG AGE , Danny Lewin brandished what his parents called “extraordinary vigor,” building impenetrable fortresses, constructing homemade computers, and climbing the foothills surrounding his early home in Englewood, Colorado. The Lewin family enjoyed an enviable, middle-class existence in the suburb of Denver, where they settled just before Danny, their eldest son, was born on May 14, 1970. Both Charles and Peggy, his parents, worked in medicine, Charles as a child and adolescent psychiatrist with a busy private practice and Peggy as a pediatrician for the Denver hospital health program. They owned a spacious home—a contemporary-style house they designed—in the quiet neighborhood of Greenwood Village, filled with young families. They attended Temple Sinai, a Reform Jewish synagogue where Danny celebrated his bar mitzvah. As an eighth grade student at Cherry Creek Middle School, Danny was a popular kid: he skied, flirted with girls, and excelled in both academics and athletics. The three Lewin boys—Danny, Jonathan, and Michael—were all extraordinarily gifted. But of the brothers, Danny had seemingly limitless talents of such broad scope they were often a study in contradiction. With thick, beefy hands like bear paws, he could effortlessly bark orders with the intensity of a drill sergeant yet also sing so beautifully he landed starring roles in the musicals staged at his synagogue, often committing all his lines to heart the night before the performance. The only thing he couldn’t do well, according to his parents, was play soccer, which frustrated him to no end. Peggy and Charles Lewin created a household that thrived on intellectual pursuits. Charles taught the boys music, literature, art, and science. For the Lewins, learning was a game—and Charles was the ringleader. He could turn almost anything, even routine family chores and meals, into an educational experience. Michael and Jonathan remember their initial dismay when their father pasted over the cartoons on the backs of their cereal boxes with math puzzles and snippets from Scientific American magazine. His nighttime stories became an event worth going to bed for; he would spin some fabulous tale into a problem-solving game, delighting and challenging his sons. “We enjoyed it,” said Michael Lewin. “My father always pushed us to excel; he wanted us to be interested in real things and not just sit around and listen to the television.” Charles Lewin also introduced his sons to technology, inspiring in all of them an early interest in computers. **Before the advent of the personal computer (PC) in the early 1970s, Charles purchased a kit to assemble a computer himself. The Altair didn’t have a keyboard or a video display, but, for early enthusiasts like Charles, the ability to input data into the machine was thrilling.** In 1979, he brought home an Apple II, one of the first successful PCs designed by Apple co-founder Steve Wozniak. The Lewins became the only family in their neighborhood to own one, and the three boys—then ages five, seven and nine—spent countless hours teaching themselves how to program it. Over the years, however, Charles Lewin had begun to feel increasingly dissatisfied with his comfortable Colorado life. It wasn’t unhappiness he suffered, but a nagging sense of restlessness. “I felt there had to be more to life,” explained Charles. A prolific poet (who later self-published several collections of his work under the pen name Yaakov Ben David), Charles was a serious, introspective man who loathed the trappings of material wealth. In search of a greater purpose in life, he turned to Zionism, the international movement for the return of the Jewish people to their homeland. Gradually, Charles’s identification with Zionism intensified, and he began to seriously consider a move to Israel. The longer he remained in Colorado, the more he felt his Jewish identity being threatened by the shadowy specter of assimilation. The best thing for himself and his family, he believed, was for them to “make aliyah ,” or immigrate to Israel. Translated literally from Hebrew, aliyah means “ascent”—a term used to describe the repatriation of the Jews to Israel. Returning to the their homeland has long been an aspiration for Jews and a core belief of Zionism. It was rare for Americans to make aliyah , and those who did were usually motivated by deep ideological yearnings. In 1984, when Charles older children was almost unheard of. That year, approximately 2,827 American families made aliyah, and, of those, it’s estimated only a fraction remained permanently in Israel—the majority returning to America frustrated by the challenges of relocating and missing the ease of life back home.

Paul Adin Lewis (1879-1929) was an American pathologist and **associate member of the Rockefeller Institute for Medical Research**. He was best known for his work in viral and bacterial pathology.[1]

Life

Lewis was born in Chicago and grew up in Milwaukee, Wisconsin. He was the eldest son of Dr. Clinton H. Lewis, a practicing physician. Lewis's sister, Dr. Marian Lewis, also practiced medicine in Milwaukee.[citation needed]Lewis married Louise Durbin in 1906. They had two children, Hobart and Janet.[2]

Education and career

After attending the University of Wisconsin–Milwaukee, Lewis went on to earn his M.D. from the University of Pennsylvania in 1904. While still an undergraduate, he chose to pursue a career as a laboratory scientist and never practiced medicine.[2]

Following stints at Boston City Hospital, the Massachusetts State Board of Health, Harvard University, and the Rockefeller Institute for Medical Research, Lewis became laboratory director at the Henry Phipps Institute and professor of experimental pathology at the University of Pennsylvania (1910-1923). He served in the U.S. Naval Reserve (1917-1921), attaining the rank of commander, and served during the 1918-19 Spanish flu pandemic.[3] Lewis rejoined the Rockefeller Institute in Princeton, New Jersey, in 1923 and worked in the department of animal pathology until his death six years later.[4]

Scientific contributions

From his graduation in 1904 to his death in 1929, Lewis published 78 articles on topics such as anaphylaxis, poliomyelitis, chemotherapy, and tuberculosis.[3] **With [Dr. Simon Flexner (born 1863)] in 1910, Lewis discovered via a series of experiments that poliomyelitis is caused by a virus, the virus can be transmitted between monkeys, and exposure makes survivors immune to reinfection. These discoveries helped pave the way for development of a polio vaccine in 1955.**[5] With Richard E. Shope in 1931, Lewis discovered an influenza A virus that could infect both pigs and humans. This virus turned deadly when mixed with Haemophilus influenzae, illuminating the origins of the Spanish flu.[6] Lewis's later work centered on tuberculosis, heredity, and allergies in guinea pigs.[2] Lewis served as director of the National Tuberculosis Association[3] and member of the American Association of Pathologists and Bacteriologists, Association of American Physicians, and American Association for the Advancement of Science.[4]

Death

In 1929, Lewis died of yellow fever in Bahia, Brazil, while investigating the disease under the auspices of the Rockefeller Foundation's International Health Board.[2] A telegram reporting his death to the Foundation noted that Lewis probably contracted yellow fever through a laboratory infection. [**Dr. Richard Edwin Shope (born 1901)**], who was mentored by Lewis at the Rockefeller Institute, noted to family a rumor that his mentor had somehow contaminated a cigarette with the virus entering through a cut on Lewis's lip. This theory of Lewis's untimely death mirrored some of the details of the Pulitzer Prize-winning novel Arrowsmith by Sinclair Lewis publish several years earlier in 1925.[7] Lewis is interred at the Forest Hills Cemetery in Madison, Wisconsin. The Lewis Playfield in Milwaukee's Bay View neighborhood is named in his honor.[8]

ST. LOUIS POST-DISPATCH
The Only Evening Newspaper in St. Louis With the Associated Press News Service
ST. LOUIS, TUESDAY, JULY 2, 1929.—36 PAGES.

DR. PAUL A. LEWIS MARTYR TO STUDY OF YELLOW FEVER

Member of Rockefeller Institute Dies of Disease Which Killed Colleague, Dr. Hideyo Noguchi.

WAS IN INFECTED CITY OF BRAZIL

Research Pathologist Had Also Helped in Combatting Tuberculosis and Infantile Paralysis.

By Leased Wire From the New York Bureau of the Post-Dispatch.

NEW YORK, July 2.—Dr. Paul A. Lewis, research pathologist associated with the Rockefeller Institute for Medical Research, died last Sunday at the age of 50 in Bahia, Brazil, of yellow fever, while engaged in a study of that disease, it was learned yesterday.

Like the late Dr. Hideyo Noguchi, a colleague in the Rockefeller Institute, who died under identical circumstances a year ago, he was a martyr to the attempt to find a more efficient way of preventing the dread fever. He had gone to Bahia, where it is particularly prevalent, to study the effect of the South American variety of the yellow fever bacillus on both man and monkey.

Dr. Noguchi's death came in May, 1928, in Acera, a fever-stricken town on the African Gold Coast, just after he had succeeded in identifying its cause, a deadly bacillus of the family letospira, which is carried by the mosquito. He was seeking to discover the relationship between African and South American yellow fever.

Dr. Lewis was among the most eminent research bacteriologists in the country. In 1916 he was summoned to New York by the health department as one of a commission to fight the infantile paralysis then raging in the city. At that time he was professor of pathology in the University of Pennsylvania and head of the laboratories of the Phipps Institute.

In 1925 he was allied with a group of distinguished pathologists on the Research Committee of the National Tuberculosis Association, who began in that year to wage a war against the "white plague" which has since served to reduce the mortality from it considerably. He is described as a pioneer in the therapy of tuberculosis.

He was educated in the University of Wisconsin and the Wisconsin College of Physicians and Surgeons, and received his M. D. diploma from the University of Pennsylvania in 1904. From 1908 to 1910 he was an associate in pathology in the Rockefeller Institute. Thereafter he taught and did research in several medical colleges. In 1923 he became associated with the animal pathology department of the Rockefeller Institute in Princeton, N. J. He was a commander in the United States Naval Reserve from 1917 to 1921.

Dr. Lewis is survived by his wife and two children.

The Great Influenza: The Epic Story of the Deadliest Plague in History - John M. Barry (2004)

Part X. ENDGAME

Chapter 36

IN THE FIRST YEARS after the pandemic, Paul Lewis continued to head the Henry Phipps Institute at the University of Pennsylvania.

Yet Lewis was not a happy man. He was one of those who continued to believe that B. influenzae caused the disease and continued to work on it after the epidemic passed. There was irony in that, since he had initially been reluctant to embrace its etiological role, suspecting instead a filterable virus. Perhaps the chief reason for his stubbornness was his own experience. He had not only found the bacillus with consistency, but he had produced a vaccine that seemed to work. True, the navy had administered a vaccine prepared according to his methods to several thousand men and it had proven ineffective, but he had not made that vaccine himself. A smaller batch that he had personally prepared and tested—during the peak of the epidemic, not in its later stages when many vaccines seemed to be working only because the disease itself was weakening—had given solid evidence of effectiveness. Only three of sixty people who received the vaccine developed pneumonia, and none died; a control group had ten pneumonias and three deaths.

Those results deceived him. In the past he had not always made the right scientific judgment—no investigator does—but this may have been his first significant scientific error. And it seemed to mark the beginning of a downhill slope for him.

That was not obvious at first. He had already built an international reputation. The German scientific journal Zeitschrift für Tuberkulose translated and reprinted his work. In 1917 he was invited to give the annual Harvey Lecture on tuberculosis, a great honor; Rufus Cole, for example, would not receive that invitation for another decade. Eighty-five years later, Dr. David Lewis Aronson, a scientist—whose father, a prize-winning scientist, had worked in the best European laboratories and considered Lewis the smartest man he ever met and gave his son Lewis's name—recalled reading that speech: "You could see Lewis's mind working, the depth of it, and vision, going well beyond what was going on at the time."

Lewis's views had broadened indeed. His interests now included mathematics and biophysics, and, with no resources of his own, he asked Flexner to "arrange for the support" of a physicist Lewis wanted to lure into medicine to examine fluorescent dyes and "the disinfectant power of light and the penetrating power of light for animal tissues." Flexner did so, and Flexner continued to be impressed by Lewis's own work, replying by return mail when Lewis sent him a paper, saying that he would publish it in the Journal of Experimental Medicine, calling it "interesting and important."

Yet Lewis's life after the war began pulling him away from the laboratory, frustrating him. Henry Phipps, the U.S. Steel magnate who had given his name to the institute Lewis headed, had not endowed it generously. Lewis's own salary had risen well enough, from $3,500 a year when he started in 1910 to $5,000 just before the war. Flexner still considered him vastly underpaid and saw to it that, immediately after the war, the University of California at Berkeley offered him a professorship. Lewis declined, but Penn raised his salary to $6,000, a substantial income at that time.

But if his own salary was more than adequate, he needed to fund an entire institute, even if a small one. He needed money for centrifuges, glassware, heating, not to mention "dieners"—the word still in use for technicians—and young scientists. He needed to raise the money for all that himself. As a result Lewis more and more found himself drawn into the social milieu of Philadelphia, raising money, being charming. More and more he was becoming a salesman, selling both the institute and himself. He hated it. He hated the time it took from the laboratory, the drain of his energies, the parties. And the country was in the midst of a deep recession, with four million soldiers suddenly thrown back onto the job market, with the government no longer building ships and tanks, with Europe desolate and unable to buy anything. Raising money was more than just difficult.

In 1921 the University of Iowa approached him. They wanted to become a first-class research institution, and they wanted him to run the program, to build the institution. The state would supply the money. Flexner was more than just a mentor to Lewis, and Lewis confided in him that the Iowa job seemed "heavy, safe and of limited inspiration. You know very well that I do not thrive on routine." And at Phipps, "Some of the work underway has great potential I believe.... You will see that I am trying to convince myself that I have a right to gamble here as against a rather dull safe outlook at Iowa City. A word from you would be much appreciated."

Flexner advised him to accept the offer: "All I have heard of the medical situation at Iowa City is favorable,...a pretty sharp contrast to the [situation] in Philadelphia. It is definite and has the elements of permanency.... I have no doubt under the influence of your vigorous guidance, the department—although quite large—over which you would preside would become so notable that the State would stand back of you in any enlargement."

He did not tell Lewis how well he thought the job might suit him, how extraordinary his gifts for a job like that were. But Flexner did tell a senior colleague that Lewis "might really come to exercise a real influence in medical teaching and research." There was perhaps some of what Welch had in him, that Lewis had "quite unusual gifts of exposition." He had broad knowledge, perhaps he even leaked knowledge, and, whether he realized it or not, he could inspire. Indeed, Flexner believed he could "be master of the field."

The University of Pennsylvania countered the offer: it gave him a new title, raised his salary to $8,000, guaranteed it for five years, and guaranteed funding for the institute itself for two years. He stayed. Flexner congratulated "you and the University especially on your new honor. Will the new chair add to your University responsibility?"

It would. Partly for that reason Lewis remained restless. He had rejected the Iowa position because, though it might allow him to build a major institution, it would keep him out of the laboratory. Now he found himself in much the same situation at Penn. He detested maneuvering with or around deans and he continued to play the role of social creature. Scientists were the new thing, Faustian figures able to create worlds and fashionable to show off on the Main Line. Lewis hated being shown off. There was tension at home with his wife as well. How much of that came from his research frustrations, how much because his wife liked the Philadelphia society that he wanted no part of, how much because his wife simply wanted more of him, it is impossible to know.

One research project in particular seemed to be going well, and he wanted to attend to it, and give up everything else. He envied not only Avery's ability to concentrate on one thing but also his opportunity to do so. For Lewis everything seemed to press upon him. Indeed, everything seemed ready to explode.

In 1922 Iowa offered him the position again. This time he accepted. He felt a responsibility to leave Phipps in good shape and recruited Eugene Opie from

Washington University to replace him. Opie had if anything an even greater reputation than his own.

Flexner had always respected Lewis, yet there had always been a gap between them. They had been getting closer. At one point Flexner wrote him, "Some time do let me take a little trouble for you." Lewis confided in return, "You have stood in the light of 'father' to me." Now, when Opie agreed to replace Lewis at Phipps, Flexner seemed to see Lewis in a new light, capable not only as a scientist but as someone who could play another game well, telling him, "Opie surprised me. I supposed him a fixture in St. Louis. If you prepared the way for so good a man at the Phipps Institute, you may well feel gratified."

Lewis did not feel gratified. He remained restless and discontented. What he really wanted was to be shut of everything, everything except the laboratory. Perhaps without quite realizing it, he had been moving toward a crisis. Again he told Flexner that what he really wanted more than anything was to work at his laboratory bench. He was shut of Philadelphia. Now he had to get himself shut of Iowa.

In January 1923 he wrote Flexner, "It is quite clear to me today that I am entitled again for a short time at least to cultivate my personal interests…. I am giving up my place here and all of my plans for a future in Philadelphia…. I have written to President Jessop, of the University of Iowa, telling him of my change of plan and that that is also in the discard…. I am going to try my best to develop the opportunity for a year of study in some place as far removed from any question of 'affairs or position' as possible…. I cannot make it too plain that for the coming year I am seeking no position in the conventional sense of the word. What I really want is…the rehabilitation of a more or less vacant mind."

He was quitting everything, walking away from position, prestige, and money, walking into the wilderness with no guarantee of anything, stripping himself naked at the age of forty-four with a wife and two children. He was free.

Where he had been happiest in his life, where he had done the best science, had been at the Rockefeller Institute. The institute had created a Division of Animal Pathology in Princeton, close to Philadelphia. Theobald Smith, the same man who had rejected Welch's offer to become the first head of the Rockefeller Institute itself, had left Harvard and now headed this division. Smith had also been Lewis's first mentor, and had recommended him so many years before to Flexner. Lewis explored with Smith the possibility of going to Princeton. Smith first wanted assurances that Lewis wanted "to go to work again and…that all this advertising business had not gone to [his] head." Lewis eagerly gave them.

Flexner had urged him to take the Iowa job but replied, "I shall be rejoiced to see you return to the lab where you so naturally belong and in which you will do your best, most lasting, and effective work. It seems to me a crying pity that men who have given years to the necessary preparation for a lab career should be so ruthlessly drawn away from it and made to fill executive positions." He also told Lewis that Smith was "very pleased with the prospect of having you associated with him again."

Lewis asked for no salary whatsoever, just full access to the laboratories for a year. Flexner gave him $8,000, his salary at Phipps, and a budget for laboratory equipment, filing cabinets, 540 animal cages for breeding and experimenting, and three assistants. He told Lewis he would expect nothing whatsoever from him for the year, and then they could talk again about the future.

Lewis was ecstatic: "To start with Dr. Smith again on any possible basis, takes me back to 1905—on I hope certainly a new higher level…. You will not find me lacking in effort…. I am most fortunate and happy in being able to regard myself as entirely in the hands of you two men who, without distinction, and excepting only my parents, have given me the means and the education and the direction. Few have such a chance to renew their youth. My only hope is that I continue to deserve your confidence."

Princeton then was still surrounded by farms and countryside. It was peaceful, almost bucolic. The Rockefeller facility was not far from the campus of Princeton University, which was still transforming itself from the finishing school for gentlemen that F. Scott Fitzgerald described to the intellectual center that it would not fully become until a decade later, when Flexner's brother Abraham started the Institute for Advanced Study with Einstein as its first member. But if the setting was bucolic, if crops grew and assorted animals—not simply guinea pigs or rabbits but cattle, pigs, and horses—grazed only yards from the laboratories, the Rockefeller part of Princeton brewed intensity. Smith was continuing to produce world-class work. Just being around him energized Lewis. For the first time since he left the Rockefeller Institute, he felt at home. Yet he was alone. His wife and children stayed in Philadelphia. He was alone to work, alone to go to the laboratory in the middle of the night, alone with his thoughts.

In nearly a year, however, he produced nothing. Flexner and he did discuss his future. He was forty-five years old. His next move would likely be his last one. He could still return to the University of Pennsylvania if he chose. He did not so choose, telling Flexner, "I can only repeat that I am free of any entanglement there, even of sentiment." The University of Iowa had also extended its offer once again and once again raised the salary. But what he wanted was to stay at Rockefeller. He had made little progress on the tuberculosis project he had brought with him from Philadelphia, but, more importantly, he had, he assured himself as much as Flexner, rejuvenated himself. He informed Flexner that, despite the higher salary at Iowa, "My only interest in 'position' is [here]."

Lewis's presence fitted perfectly into Flexner's own plans. Flexner explained, "I have always believed that our departments should not be one man affairs." In New York a dozen or more extraordinary investigators led groups of younger researchers, each group working on a major problem. The Princeton location had not developed similarly; beyond Smith's own operation, it had not filled out. Flexner told Lewis, "Your coming…[offers] the first chance to make a second center there."

Further, Smith would turn sixty-five that year. Flexner and Smith and even Welch hinted to Lewis that he might succeed Smith when he retired. Flexner suggested that Lewis stay one more year under a temporary arrangement, and then they would see.

Lewis told Flexner, "I am secure as I never was before." He believed he was home. It would be his last home.

If Lewis was going to build a department, he needed a young scientist—someone with more than just laboratory skills, someone with ideas. His contacts in Iowa urged him to try a young man they thought would make a mark.

Richard Shope was the son of a physician who was also a farmer. He had gotten his medical degree at the University of Iowa, then spent a year teaching pharmacology at the medical school and experimenting on dogs. An outstanding college track athlete, tall, a man's man at ease with himself—something Lewis never quite seemed to be—Shope always maintained contact with the wild, with the forest, with hunting, not only in the laboratory but with a gun in his hands. His mind had a certain wildness, too, like a small boy playing with a chemistry set hoping for an explosion; he had more than an inquiring mind, he had an original one.

Years later Thomas Rivers, the virologist who not only succeeded Cole as head of the Rockefeller Institute Hospital but served as president of four different scientific associations, said, "Dick Shope is one of the finest investigators I have ever seen…. A stubborn guy, and he is tough,…Dick would no sooner start to work on a problem than he would make a fundamental discovery. It never made one bit of difference where he was." In World War II, Rivers and Shope landed on Guam soon after combat troops secured it (in Okinawa they would come under fire) to investigate tropical diseases that might threaten soldiers. While

there, Shope occupied himself by isolating an agent from a fungus mold that mitigated some viral infections. Ultimately he was elected to membership in the National Academy of Sciences.

Yet even with Shope's help, Lewis's work did not go well. It was not for lack of intelligence on Lewis's part. Shope knew Welch, Flexner, Smith, Avery and many Nobel laureates well, yet he considered Lewis a notch above; like Aronson, the prize-winning scientist who had worked at the Pasteur Institute and knew Lewis at Penn, Shope considered Lewis the smartest person he ever met.

Lewis had reached some tentative conclusions in Philadelphia about tuberculosis. He believed that three, and possibly four, inherited factors affected the natural ability of guinea pigs to produce antibodies—i.e., to resist infection. He had planned to unravel precisely what the nature of these factors was. This was an important question, one that potentially went far beyond tuberculosis to a deep understanding of the immune system.

But when he and Shope repeated the Philadelphia experiments they got different results. They examined every element of the experiments to see what might explain the differences and repeated them again. Then they repeated the process and the experiments again. Again they got differing results, results from which it was impossible to draw a conclusion.

Nothing in science is as damning as the inability of an outside experimenter to reproduce results. Now Lewis himself could not reproduce the results he had gotten in Philadelphia, results he had depended upon. Much less could he build upon and expand them. He had run into a wall.

He began plugging away at it. Shope too plugged away at it. Both of them had the tenacity to stay after a thing. But they made no progress.

More distressing to Smith and Flexner, who watched closely, was the way Lewis was approaching the problem. His failures seemed to confuse him. Unlike Avery, who broke his problems down into smaller ones that could be solved and who learned from each failure, Lewis seemed simply to be applying brute force, huge numbers of experiments. He sought to add other scientists with particular expertise to his team, but he did not define what precise role new people would play. Unlike Avery, who recruited people with specific skills to attack a specific question, Lewis seemed simply to want to throw resources at the problem, hoping someone would solve it.

He seemed desperate now. Desperate men can be dangerous, and even feared, but they are rarely respected. He was losing their respect, and with that would go everything.

As Lewis approached the end of his third year in Princeton, Smith confided his disappointment to Flexner: "He is perhaps aiming higher than his training and equipment warrant and this results in a demand to surround himself with technically trained chemists, etc. This is what Carrel"—Alexis Carrel at the Rockefeller Institute in New York, who had already received the Nobel Prize—"is doing but Carrel has another type of mind and gets results from his organization. A closely-knit group requires that the ideas come from the head man."

Nor did Lewis seem to recognize as worth pursuing potentially promising side questions his experiments raised. His explanation for his failures, for example, was that the diet of the guinea pigs was different in Princeton than it had been in Philadelphia. This was potentially significant, and it was possible he was correct. The relationship between diet and disease had been noted before but chiefly in terms of outright diet deficiencies that directly caused such diseases as scurvy and pellagra. Lewis was thinking about far more subtle and indirect linkages between diet and disease, including infectious disease. But instead of pursuing this line of inquiry, Lewis continued to pound away at his old one. He did so without result. He reported to the Board of Scientific Directors, "I have planned no change in my line of work for the coming year."

Flexner wanted to hear something different. Lewis was making himself a marked man, marked in no good way. It wasn't Lewis's failures that did so; it was the manner in which he was failing—dully, without imagination, and without the gain of knowledge elsewhere. Lewis had shown enough, or failed to show enough, that Flexner had already made one judgment. When Smith retired, Lewis would not replace him.

Flexner wrote him a chilling letter. In a draft Flexner was brutal: "There is no obligation expressed or implied in the Institute's relation to you, or your relation to the Institute, beyond this service year period…. As the Iowa chair is still open and you are very much wanted to fill it, and the University of Iowa would make a supreme effort to secure you, I believe it due you to be minutely informed just what the position the Board of Scientific Directors has taken with reference to you…. There was doubt expressed about your future in general."

Flexner did not send that letter. It was too harsh even for him. Instead he simply informed Lewis that the board was "unequivocally opposed to the appointment of one primarily a human pathologist"—which Lewis was—"to the directorship of the Department of Animal Pathology," and that therefore he would not replace Smith. But he also warned Lewis that the board would not elevate him to the rank of a "member" of the institute, the equivalent of a tenured full professor. He would remain only an associate. His appointment expired in six months, in mid-1926, and the board would give him a three-year appointment into 1929. Perhaps he should accept the Iowa offer after all.

In Faust, Goethe wrote, "Too old am I to be content with play, / Too young to live untroubled by desire."

Lewis was too old to play, too young to be untroubled by desire. Reading Flexner's letter had to have been a crushing blow. He had expected to be told he would succeed Smith. He had been certain he would be elevated to the rank of "member" of the institute. From the laboratory, he drew his identity, and yet now the laboratory gave him not sustenance but cold rebuff. The two men he most admired in the world, two men he had thought of as scientific fathers—one of whom he regarded as almost a father—had judged that he lacked something, lacked a thing that would entitle him to join their brotherhood, to become a member.

By now Lewis's family had moved to Princeton, but his marriage was no better. Perhaps the fault lay entirely within him, within what was now not so much a failing ambition as a failing love.

He declined the Iowa job once again. He had always been willing to gamble. Now he gambled on proving himself to Flexner and Smith.

For the next year and a half, he worked, at first feverishly but then…Something in him made him withdraw. His son Hobart, then fourteen years old, was having difficulties emotionally and difficulties in school, although a change of schools seemed to help. And Lewis had a car accident that broke his concentration.

He accomplished little. Again his failures were not like those that Avery would confront for nearly a decade. Avery was attacking the most fundamental questions of immunology and, ultimately, genetics. From each failed experiment he learned, perhaps not much but something. And what he was learning went beyond how to fine-tune an experiment. What he was learning from his failures had large ramifications that applied to entire fields of knowledge. One could argue that none of Avery's experiments failed.

Lewis was simply foundering. He had spent hour after hour in the laboratory. It had always been his favorite place, his place of rest, of peace. It gave him no

Lewis was simply foundering. He had spent hour after hour in the laboratory. It had always been his favorite place, his place of rest, of peace. It gave him no peace now. He began to avoid it. His marriage was no better; his wife and he barely communicated. But he found other things to do, gardening, carpentry, things he had never attended to before. Perhaps he hoped getting away would clear his mind, allow him to see through the fog of data. Perhaps he thought that. But his mind never seemed to go back to the problem.

In August 1927, he confessed to Flexner, "I feel I have not been very productive—certainly I feel that I have had a meager return for a lot of hard work—but some way everything I have touched in the hope it would go faster than the very slow jobs I have been on for so long has either been a wash-out or turned into some other big [problem]."

Then he said something even more striking. He was no longer going to the laboratory: "I am spending most of my time on an old house and garden I have gotten hold of."

Flexner replied, for him, gently. Lewis was now more than a year into his three-year contract extension. Flexner warned that his tuberculosis work "has been under way as your major problem for four years. The outcome, even if continued many years longer, is uncertain and the yield of side issues, often the most fruitful of all, has been small. I do not believe in sticking to a rather barren subject. One of the requisites of an investigator is a kind of instinct which tells him quite as definitely when to drop, as well as when to take up a subject. Your time can be more promisingly employed along another major line."

Lewis rejected the advice.

On September 30, 1918, J. S. Koen, a veterinarian with the federal Bureau of Animal Industry, had been attending the National Swine Breeders Show in Cedar Rapids. Many of the swine were ill, some of them deathly ill. Over the next several weeks he tracked the spread of the disease, the deaths of thousands of swine, and concluded they had influenza—the same disease killing humans. Farmers attacked his diagnosis; it could cost them money. Nonetheless, a few months later he published his conclusion in the Journal of Veterinary Medicine: "Last fall and winter we were confronted with a new condition, if not a new disease. I believe I have as much to support this diagnosis in pigs as the physicians have to support a similar diagnosis in man. The similarity of the epidemic among people and the epidemic among pigs was so close, the reports so frequent, that an outbreak in the family would be followed immediately by an outbreak among the hogs, and vice versa, as to present a most striking coincidence if not suggesting a close relation between the two conditions."

The disease had continued to strike swine in the Midwest. In 1922 and 1923, veterinarians at the Bureau of Animal Industry transmitted the disease from pig to pig through mucus from the respiratory tract. They filtered the mucus and tried to transmit the disease with the filtrate. They failed.

Shope observed swine influenza during a trip home to Iowa. He began investigating it. Lewis helped him isolate a bacillus virtually identical to B. influenzae and named it B. influenzae suis. Shope also replicated the experiments by the veterinarians and began to move beyond them. He found this work potentially very interesting.

Lewis's own work, however, continued to founder. Flexner and Smith had kept their assessments of it confidential. As far as the rest of the world—even including Shope—knew, they held him in the highest regard. In June 1928, for the fourth time, the University of Iowa made Lewis still another offer, an outstanding offer. Flexner urged him to accept. Lewis replied that his "compelling" interest remained at Princeton.

Flexner called Smith to discuss "our future Lewis problem." They could not understand him. Lewis had produced nothing in five years. They in fact did have the highest regard for him—just no longer for his laboratory skills. Flexner still believed that Lewis had true gifts, broad and deep vision, an extraordinary ability to communicate and inspire. Flexner still believed that Lewis could become a dominant figure in medical teaching and research. Of that field, he could still be master.

Lewis had shown at least some of what Welch had. Perhaps he had much of it. And perhaps in the end he also lacked what Welch lacked, the creativity and organizational vision to actually run a major laboratory investigation.

Two days after Flexner and Smith talked, Flexner sat down with Lewis. He was blunt. But he assured Lewis the bluntness "was a conclusion placed before [you] in all kindness." The prospect of Lewis's becoming a member of the institute was a distant dream. His research had been "sterile" for the past five years. Unless it yielded something solid and important in the next year, he would not be reappointed even to a temporary position. He was approaching fifty years of age and Flexner told him, "The chances of [your] changing in the direction of more fertile ideas [are] small." He also said Lewis had not acted with "energy and determination." He had not fought. Then, most painfully, Flexner said he was "not essentially of the investigator type."

Flexner urged him—indeed, all but ordered him—to take the Iowa position. It was an extraordinary offer: $10,000 a year salary—more than double the median income for physicians—and a free hand in organizing a department. Flexner assured him that he still believed he had great gifts. Great gifts. He could still make a huge contribution, a significant and important contribution. At Iowa he could become a major figure, inspire respect, and be far happier.

Lewis listened quietly and said little. He did not remonstrate or argue. He was almost passive, yet firm. There was a cold, unreachable center within him. Regarding Iowa, that was settled. He would reject the offer. He had no interest in anything but the laboratory. He hoped in the next year to justify reappointment.

After the conversation Flexner was frustrated, frustrated and angry. "I put all the pressure I could upon him but without avail," he wrote Smith. "My notion is our obligations to Lewis are now fulfilled and that unless a great change takes place it will be our duty to act decisively next spring. He has been a real disappointment to me…. I left no doubt as to the risk he takes, and he left me no doubt that he understands and accepts that risk."

A few months before Flexner's brutal conversation with Lewis, Hideyo Noguchi had gone to Ghana to investigate yellow fever. Noguchi was as close to a pet as Flexner had. They had first met almost thirty years earlier, when Flexner was still at Penn and gave a speech in Tokyo. Uninvited, Noguchi had followed him to Philadelphia, knocked on his door, and announced he had come to work with him. Flexner found a position for him, then took him to the Rockefeller Institute. There Noguchi had developed an international reputation, but a controversial one.

He had done real science with Flexner, for example, identifying—and naming—neurotoxin in cobra venom. And he had claimed even more significant breakthroughs on his own, including the ability to grow polio and rabies viruses. (He could not have grown them with his techniques.) Rivers, also at Rockefeller and the first person to demonstrate that viruses were parasites on living cells, questioned those claims. Noguchi responded by telling him that a man who had done research for a long time had scars that he could never get rid of. Later Rivers discovered a significant unrelated mistake in his own work and confessed to Noguchi that he planned to retract his paper. Noguchi advised against it, saying it would take fifteen years for anyone else to find out he was wrong. Rivers was astounded, later saying, "I don't think Noguchi was honest."

Noguchi's most important claim, however, was to have isolated the pathogen that caused yellow fever. It was a spirochete, he said, a spiral-shaped

bacterium. Years before, Walter Reed had seemed to prove that a filterable virus caused the disease. Reed was long dead, but others attacked Noguchi's findings. In response to one such attack, Noguchi wrote Flexner, "[H]is objections were very unreasonable…. I am not certain whether these Havana men are really interested in scientific discussion or not."

Noguchi did not lack courage. And so he went to Ghana to prove himself correct.

In May 1928 he died there, of yellow fever.

Noguchi's death came one month before Flexner and Lewis had their conversation. It attracted international attention, made the front pages of newspapers around the world, inspired glowing tributes in all the New York papers. For Noguchi, it was a Viking funeral, a blazing glory that obliterated all questions about the quality of his science.

The entire Rockefeller Institute reeled from the loss. Despite any scientific controversies, Noguchi had been buoyant, enthusiastic, always helpful, universally liked. Both Flexner and Lewis suffered in particular. Noguchi had been, literally, like a son to Flexner. Lewis had known him well, very well, going back to his first happy days in New York.

Noguchi's death also left open the question of whether he had in fact isolated the pathogen that caused yellow fever. The institute wanted that question answered.

Shope volunteered to do it. He was young and believed himself invulnerable. He wanted action. He wanted to investigate yellow fever.

Flexner refused to allow him to go. Shope was also only twenty-eight years old, with a wife and an infant son. It was too dangerous.

Then Lewis volunteered. The scientific question remained, and it was a major one. Who was more qualified to investigate it than he? He had proven himself expert at cultivating bacteria and, even more important, he had proven that polio was a viral disease. Noguchi notwithstanding, it seemed a virus did cause yellow fever. And, important as the question was, it also had built-in limits; it was the kind of narrow and focused science that Flexner still had faith in Lewis to answer.

Lewis's wife, Louise, objected. The laboratory had taken him away from her and their two children enough. She was already furious at him for once again declining the Iowa position. But this…this was something else.

Lewis had never listened to her. They had not had a real marriage for a long time. For him, this solved every problem. If he succeeded, he would restore himself in Flexner's eyes. Five years before he had resigned from the Phipps Institute and simultaneously withdrawn his acceptance of the Iowa offer without any other prospects. All that he had done in order to do the one thing he loved, return to the laboratory. He was willing to gamble again. He was energized again. And he was more desperate than ever.

Instead of Ghana, however, he would go to Brazil. A particularly virulent strain of yellow fever had surfaced there.

In late November 1928, Flexner came to Princeton to see Lewis off. Flexner's attitude toward him had already seemed to change. He was willing again to talk about the future. He also wanted, he said, to "learn about Shope's Iowa work." Shope had recently observed an extraordinarily violent influenza epizootic—an epidemic in animals—in swine. The overall mortality of the entire local pig population had reached 4 percent; in some herds mortality had exceeded 10 percent. That very much sounded like the influenza pandemic in humans a decade earlier.

A month later Lewis sailed for Brazil. On January 12, 1929, Frederick Russell, the colonel who had organized much of the army's scientific work for Gorgas and who now worked for a Rockefeller-sponsored international health organization, received a cable saying Lewis had arrived and was well. The institute relayed the news to his wife, who had been so angry at Lewis's departure that she had wanted nothing to do with the Rockefeller Institute and returned to Milwaukee, where both she and Lewis had grown up. Each week Russell was to receive news of Lewis and send it on to her.

Lewis located his laboratory in Belem, a port city on the Para River, seventy-two miles from the ocean but the main port of entry into the Amazon Basin. Europeans settled there in 1615, and a rubber boom in the nineteenth century had filled the city with Europeans while Indians went back and forth into the interior in dugout canoes. It was steamy, equatorial, and received as much precipitation as any area in the world.

On February 1, Lewis wrote Flexner, "Arrived here on Tuesday and went right to work…. [H]ave been setting up my own shop here, awaiting materials, having additional screening prepared, etc…. Should be started at something by early next week I hope."

He seemed the old Lewis, energetic and confident. And each week Russell received a two-word wire: "Lewis well." He received them through February, March, April, and May. But if Lewis was well, he sent no word about his research; he gave no sign that work was going well.

Then, on June 29, Russell sent a note hand-delivered by messenger to Flexner: "The following message from Rio de Janeiro, regarding Dr. Paul Lewis, was sent to me today, with the request that it be delivered to you. 'Lewis's illness began on June 25th. Doctors state it to be yellow fever. Condition of June 28th, temperature 103.8, pulse 80…' The Foundation is sending the message to Dr. Theobald Smith and also to Mrs. Lewis at Milwaukee."

Even as Russell sent that note to Flexner, Lewis was in agony. He had vomited violently, the nearly black vomit of the severe cases; the virus attacked the mucosa in his stomach, which bled, giving the vomit the dark color; it attacked the bone marrow, causing violent aching. An intense, searing headache gave him no rest, except perhaps when he was delirious. He had seizures. His colleagues packed him in ice and tried to keep him hydrated but there was little else they could do.

The next day another wire came: "Lewis condition critical. Anuria supervened Saturday."

His kidneys were failing and he was producing no urine. All the toxins that the body normally rid itself of were now building up in his system. Later that same day, Russell received a second wire: "Lewis on fourth day of illness. Marked renal involvement." He was becoming jaundiced, taking on the classic color that gave the disease its name. Symptom by symptom, step by step his body was failing.

June 30, 1929, was a Sunday. All day Lewis suffered, writhed in delirium. He went into a coma. It was his only relief. It was the fifth day of his illness. There would not be a sixth.

Shortly before midnight Dr. Paul A. Lewis found release.

An unsigned wire to Russell reported, "Typical yellow fever. Probably laboratory infection. Wire instructions regarding body."

Shope walked down Maple Street on the edge of the Princeton campus to inform Lewis's wife, who had come back from Milwaukee, and son Hobart, now a

Shope walked down Maple Street on the edge of the Princeton campus to inform Lewis's wife, who had come back from Milwaukee, and son Hobart, now a college student who had remained in Princeton.

Lewis's widow gave simple and explicit instructions. She was returning immediately to Milwaukee and wanted the body shipped directly there, where those who cared about Paul were. She specifically stated that she wanted no memorial service held at the Rockefeller Institute, in either New York or Princeton.

There was none.

Shope accompanied the body to Wisconsin. The business manager of the Rockefeller Institute asked him, "I wonder if you could arrange when you arrive to order some flowers for the service for Dr. Lewis."

The flowers came, with a card signed "the Board of Scientific Directors of the Rockefeller Institute."

Lewis's daughter, Janet, wrote the thank you note, addressing it "Dear Sirs." Her mother could not bring herself to have any contact with the institute, particularly a thank you note. The institute paid Lewis's salary to her through June 1930 and also paid his son Hobart's college tuition. (Like his grandfather and aunt Marian, the first woman to graduate from Rush Medical College in Chicago, he became a physician—but a clinician, not a scientist.)

In the next report to the Board of Scientific Directors of the Rockefeller Institute—a board which now included Eugene Opie, whom Lewis had recruited as his successor at Phipps—Flexner noted that one scientist's resignation "which is much regretted, left the study of light phenomena unprovided for."

Lewis had originally suggested that work to Flexner. Flexner mentioned a "recrudescence of poliomyelitis." Lewis had proved that a filterable virus caused that disease.

Flexner went through item after item concerning the institute. He pointed out "a pressing problem was the one in connection with the still unfinished work of Dr. Noguchi." He made no mention of Paul A. Lewis, no mention of Dr. Lewis at all.

Later Flexner received Lewis's autopsy report and news that researchers at the institute in New York had succeeded in transmitting Lewis's virus—they called it "P.A.L."—to monkeys and were continuing experiments with it. Flexner wrote in reply, "Thank you for sending me the report on the comparison of the Rivas and P.A.L. strains of yellow fever virus. At your convenience I should like to talk over the report with you. Dr. Cole thinks white paint and some other improvements desirable in your animal quarters. Has he spoken with you about them?"

Lewis had worked with deadly pathogens his entire adult life and had never infected himself. Since Noguchi's death everyone working with yellow fever took special care.

In the five months Lewis worked in Brazil he did not report any details of his research and his laboratory notes provided almost no information about it. He died from a laboratory accident. Somehow he gave yellow fever to himself.

Shope later told his sons a rumor that Lewis, who smoked often, had somehow contaminated a cigarette with the virus and smoked it. The virus entered the bloodstream through a cut on his lip. David Lewis Anderson recalls that his father, Lewis's friend in Philadelphia, also blamed cigarettes for Lewis's death.

Three years earlier Sinclair Lewis, no relation, won the Pultizer Prize for his bestselling novel Arrowsmith, a novel about a young scientist at a fictionalized version of the Rockefeller Institute. Everyone in medical science, especially at the institute, knew that novel. In it the main character's wife dies from smoking a cigarette contaminated by a deadly pathogen.

Flexner wrote an obituary of Lewis for Science in which he referred to "the important observations made by him in association with Sewall Wright on the hereditary factors in research in tuberculosis." Lewis's work with Wright had been carried out in Philadelphia; Flexner made no mention of anything Lewis had done in the five years since his return to the institute.

Meanwhile, Shope returned to Iowa to explore further this swine influenza, to observe still another epidemic among pigs.

In 1931, two years after Lewis's death, Shope published three papers in a single issue of the Journal of Experimental Medicine. His work appeared in good company. In that same issue were articles by Avery, one of the series on the pneumococcus that would lead to his discovery of the transforming principle; by Thomas Rivers, the brilliant virologist; and by Karl Landsteiner, who had just won the Nobel Prize. All of these scientists were at the Rockefeller Institute.

Each of Shope's articles was about influenza. He listed Lewis as the lead author on one. He had found the cause of influenza, at least in swine. It was a virus. We now know that the virus he found in swine descended directly from the 1918 virus, the virus that made all the world a killing zone. It is still unclear whether humans gave the virus to swine, or swine gave it to humans, although the former seems more likely.

By then the virus had mutated into mild form, or the swine's immune systems had adjusted to it, or both, since the virus alone seemed to cause only mild disease. Shope did demonstrate that with B. influenzae as a secondary invader it could still be highly lethal. Later he would show that antibodies from human survivors of the 1918 pandemic protected pigs against this swine influenza.

Shope's work was momentous and provocative. As soon as his articles appeared, a British scientist named C. H. Andrewes contacted him. Andrewes and several colleagues had been expending all their efforts on influenza, and they found Shope's articles compelling. Andrewes and Shope became close friends; Shope even took him hunting and fishing where he had vacationed since he was six years old, at Woman Lake, Minnesota.

In England in 1933, during a minor outbreak of human influenza, Andrewes, Patrick Laidlaw, and Wilson Smith, largely following Shope's methodology, filtered fresh human material and transmitted influenza to ferrets. They found the human pathogen. It was a filter-passing organism, a virus, like Shope's swine influenza.

Had Lewis lived, he would have coauthored the papers with Shope, and even added breadth and experience to them. He would have helped produce another of the seminal papers in virology. His reputation would have been secure. Shope was not perfect. For all his later accomplishments in influenza and in other areas, some of his ideas, including some of those pertaining to influenza, were mistaken. Lewis, if energized and once again painstaking, might have prevented those errors. But no matter.

Shope was soon made a member of Rockefeller Institute. **Lewis would likely have also been made a member. He would have been invited into the inner sanctum. He would have had all that he wanted. He would have belonged to the community of those who do science. One could consider Lewis, in a way most personal to him, the last victim of the 1918 pandemic.**

W. Ian Lipkin (born November 18, 1952) is the John Snow Professor of Epidemiology at the Mailman School of Public Health at Columbia University and a professor of Neurology and Pathology at the College of Physicians and Surgeons at Columbia University. Lipkin is also director of the Center for Infection and Immunity, an academic laboratory for microbe hunting in acute and chronic diseases.

Education

Lipkin was born in Chicago, Illinois, where he attended the University of Chicago Laboratory School and was president of the student board in 1969. He relocated to New York and earned his BA from Sarah Lawrence College in 1974. At Sarah Lawrence, he "felt that if I went straight into cultural anthropology after college I'd be a parasite. I'd go someplace, take information about myths and ritual, and have nothing to offer. So I decided to become a medical anthropologist and try to bring back traditional medicines. Suddenly I found myself in medical school."[1] Returning to his hometown Chicago, Lipkin earned his MD from Rush Medical College, in 1978. He then became a clinical clerk at the UCL Institute of Neurology in Queen Square, London, on a fellowship, and an intern in Medicine at University of Pittsburgh (1978–1979). He completed a residency in Medicine at University of Washington (1979–1981), and completed a residency in Neurology at University of California, San Francisco (1981–1984). He conducted postdoctoral research in microbiology and neuroscience at The Scripps Research Institute, from 1984 to 1990, under the mentorship of Michael Oldstone and Floyd Bloom. In his six years at Scripps, Lipkin became a senior research associate upon completing his postdoctoral work, and was president of the Scripps' Society of Fellows in 1987.

Career

Lipkin has earned the reputation of a "master virus hunter" for to his speed and innovative methods of identifying new viruses, and has been lauded by National Institute of Allergy and Infectious Diseases director [**Dr Anthony Stephen Fauci (born 1940)**]. As director of the Center for Infection and Immunity at the Mailman School of Public Health; Lipkin, from the onset of the COVID-19 pandemic, has led CII researchers collaborating with researchers at Sun Yat-sen University in China. Dr. Lipkin had also advised the Chinese government and the World Health Organization (WHO) during the 2002–2004 SARS outbreak.[2][3] Dr. Lipkin described his own infection with the SARS-CoV-2 virus, beginning mid-March 2020, which resulted in a case of COVID-19 and necessitated his recovering from the illness at home, on the podcast This Week in Virology.[4]

Lipkin was the Louise Turner Arnold Chair in the Neurosciences[5] at the University of California, Irvine from 1990 to 2001 and was recruited shortly thereafter by Columbia University. He began his current tenure at Columbia as the founding director of the Jerome L. and Dawn Greene Infectious Disease Laboratory from 2002 to 2007, which transitioned to the John Snow Professorship he holds at present.

A physician-scientist, Lipkin is internationally recognized for his work with West Nile virus and SARS, as well as advancing pathogen discovery techniques by developing a staged strategy using techniques pioneered in his lab. These molecular biological methods, including MassTag-PCR, the GreeneChip diagnostic, and High Throughput Sequencing, are a major step towards identifying and studying new viral pathogens that emerge locally throughout the globe. A major node in a global network of investigators working to address the challenges of pathogen surveillance and discovery, Dr. Lipkin has trained over 30 internationally based scientists in these state-of-the art diagnostic techniques.

Lipkin is the director for the Center for Research in Diagnostics and Discovery (CRDD), under the NIH Centers of Excellence for Translational Research program.[6] The CRDD brings together leading investigators in microbial and human genetics, engineering, microbial ecology and public health to develop insights into mechanisms of disease and methods for detecting infectious agents, characterizing microflora and identifying biomarkers that can be used to guide clinical management. Lipkin was previously the Director of the Northeast Biodefense Center,[7] the Regional Center of Excellence in Biodefense and Emerging Infectious Diseases which comprised 28 private and public academic and public health institutions in New York, New Jersey and Connecticut. Within this consortium, his research focused on pathogen discovery, using unexplained hemorrhagic fever, febrile illness, encephalitis, and meningoencephalitis as targets. He is the Principal Investigator of the Autism Birth Cohort, a unique international program that investigates the epidemiology and basis of neurodevelopmental disorders through analyses of a prospective birth cohort of 100,000 children and their parents. The ABC is examining gene-environment-timing interactions, biomarkers and the trajectory of normal development and disease. Lipkin also directs the World Health Organization Collaborating Centre for Diagnostics in Zoonotic and Emerging Infectious Diseases, the only academic center, and one of two in the US (the other is CDC), that participates in outbreak investigation for the WHO.

Lipkin was co-chair of CDC Steering Committee of the National Biosurveillance Advisory Subcommittee (NBAS).[8] The NBAS was established in response to Homeland Security Presidential Directive 21 (HSPD-21),[9] "Public Health and Medical Preparedness."

He is Honorary Director of the Beijing Infectious Disease Center, Chair of the Scientific Advisory Board of the Institut Pasteur de Shanghai and serves on boards of the Australian Biosecurity Cooperative Research Centre for Emerging Infectious Disease, the Guangzhou Institute for Biomedicine and Health, the **EcoHealth Alliance** [EcoHealth President is **Dr. Peter Daszak (born 1965)**], Tetragenetics, and 454 Life Sciences Corporation.

Lipkin served as a science consultant for the film Contagion.[11] The film has been praised for its scientific accuracy.

Early career

While not quite a medical anthropologist, Lipkin specializes in infectious diseases and their neurological impact. His first professional publication came in 1979 during the time of his fellowship in London as a letter to the Editor at the Archives of Internal Medicine (now JAMA Internal Medicine), where he poses a potential correlation between eosinopenia and bacteremia in diagnostic evaluations for a bacteremic patient.[12] While at UCL, he worked with John Newsom-Davis, who was utilizing plasmapheresis to better understand myasthenia gravis, a neuromuscular disease.[13]

In 1981, Lipkin began his neurology residency and worked in a local San Francisco clinic, which was about the time AIDS began to affect the local city population. Because of the social view of homosexual people at the time, very few clinicians would see patients with these symptoms. He "was watching many patients fall ill with AIDS. It took years for scientists to discover the virus responsible for the disease... 'I saw all of this, and I said, 'We have to find new and better ways to do this.'"[14] It was during this epidemic that Lipkin took the approach of looking for a virus' genes instead of looking for antibodies in infected people as a way to speed up the diagnosis process. By the mid-1980s, Lipkin had published two papers specifically about AIDS research[15][16] and transitioned into utilizing a more pathological approach to virus identification. He identified AIDS-associated immunological abnormalities and inflammatory neuropathy, which he showed could be treated with plasmapheresis and demonstrated early life exposure to viral infections affects neurotransmitter function.

Bornavirus

In 1989, Lipkin was the first to identify a microbe using purely molecular tools.[17][18] During his time as Chair at UC Irvine, Lipkin published several papers throughout the decade dissecting and interpreting bornavirus.[19] Once it was apparent the viral infections could selectively alter behavior and steady state brain levels of neurotransmitter mRNAs, the next step was to look for infectious agents which could be used as probes to map anatomic and functional domains in the central nervous system (CNS).[20]

By the mid-1990s, it was asserted that "Borna disease is a neurotropic negative-strand RNA virus that infects a wide range of vertebrate hosts," causing

By the mid-1990s, it was asserted that "Borna disease is a neurotropic negative-strand RNA virus that infects a wide range of vertebrate hosts," causing "an immune-mediated syndrome resulting in disturbances in movement and behavior."[21] This led to several groups across the globe working to determine if there was a link between Borna disease virus (BDV) or a related agent and human neuropsychiatric disease.[22] The group was formally called Microbiology and Immunology of Neuropsychiatric Disorders (MIND) and the multicenter, multi-national group focused on using standardized methods for clinical diagnosis and blinded laboratory assessment of BDV infection.[23] After nearly two decades of inquiry, the first blinded case-controlled study of the link between BDV and psychiatric illness[24] was completed by the researchers at Columbia University's Center for Infection and Immunity in a joint effort that concluded there is no association between the two. Lipkin noted that "it was concern over the potential role of BDV in mental illness and the inability to identify it using classical techniques that led us to develop molecular methods for pathogen discovery. Ultimately these new techniques enabled us to refute a role for BDV in human disease. But the fact remains that we gained strategies for the discovery of hundreds of other pathogens that have important implications for medicine, agriculture, and environmental health."[25]

West Nile Virus

West Nile Virus in New York

In 1999, West Nile virus was reported in two patients in Flushing Hospital Medical Center in Queens, New York. Lipkin led the team identifying West Nile virus in brain tissue of encephalitis victims in New York State[14] It was determined potential routes for the spread of West Nile virus throughout New York (and the Eastern United States) originated from predominantly mosquitoes, but also possible from infected birds or human beings. There is a high likelihood the two international airports nearby the initial reported cases were also the initial points of entry into the United States.[26] During the five years after the first reported case, Lipkin worked on a study with the National Institutes of Health (NIH) and the Wadsworth Center at the New York State Department of Health (NYSDOH) to determine how a vaccine could be developed. While they had some success with the immunization of mice with prME-LPs,[27] as of 2018, there is still no human vaccine for WNV.[28]

SARS-CoV

Sars-corona

Chinese scientists first discovered the severe acute respiratory syndrome (SARS) coronavirus in February 2003, but due to initial misinterpretation of the data, the information of the correct agent associated with SARS was suppressed and the outbreak investigation had a delayed start. Advanced hospital facilities were at the greatest risk as they were most susceptible to virus transmission, so it was the "classical gumshoe epidemiology" of "contact tracing and isolation" that brought swift action against the epidemic.[29] Lipkin was requested to assist with the investigation by Chen Zhou, vice president of the Chinese Academy of Sciences and Xu Guanhua, minister of the Ministry of Science and Technology in China to "assess the state of the epidemic, identify the gaps in science, and develop a strategy for containing the virus and reducing morbidity and mortality."[30] This brought the development of Real-time polymerase chain reaction (qPCR) technology, which essentially allowed for the detection of infection at earlier time points as the process, in this instance, targets the N gene sequence and amplify the analysis in a closed system. This markedly reduces the risk of contamination during processing.[31] Test kits were developed with this PCR-based assay analysis[32] and 10,000 were hand-delivered to Beijing during the height of the outbreak by Lipkin, whereupon he trained local clinical microbiologists on the proper usage. He became ill upon his return to the U.S. and was quarantined.[33]

Lipkin was asked to join the Defense Science Board Task Force on SARS Quarantine Guidance during the height of the SARS outbreak between 2003 and 2004, to advise the U.S. Department of Defense on steps to domestically manage the epidemic. As part of the EcoHealth Alliance, Lipkin's center worked in conjunction with an NIH/NIAID grant[34] assessing bats as the reservoir for the SARS virus. 47 publications resulted from this grant, which also included assessment on Nipah, Hendra, Ebola, and Marburg viruses. This proved to be significant research on the overall study of viral reservoirs as it was determined that bats carry coronaviruses and either directly infect humans with an exchange of bodily fluid (such as a bite) or indirectly by infecting an intermediate host, such as swine.[35] Lipkin addressed a health forum in Guangzhou in January 2004 where China Daily reported him as saying: "SARS virus is probably rooted and spread by rats."[36]

In 2016, the Chinese government awarded him the International Science and Technology Cooperation Award, the nation's top science honor for foreign scientists,[37] and in January 2020, it awarded him a medal marking the People's Republic of China's 70th Anniversary, both awards for his work during the 2002–2004 SARS outbreak and in strengthening China's public health system.[38]

MERS-CoV

Middle East respiratory syndrome (MERS) was first reported in Saudi Arabia during June 2012 when a local man was initially diagnosed with acute pneumonia and later died of kidney failure. The early reports of the disease were similar to SARS as the symptoms are similar, but it was quickly determined these cases were caused by a new strain called MERS coronavirus (MERS-CoV). Given Lipkin's expertise with the SARS outbreak in China nearly ten years prior, the Saudi Arabian Ministry of Health granted Lipkin and his lab local access to animal samples related to the initial reported cases.[39] With the rare opportunity, Lipkin's team created a mobile lab able to fit in six pieces of personal luggage and was transported from New York to Saudi Arabia via commercial flight to complete the analysis of samples.[40]

It seemed unlikely that bats were directly infecting humans, as the direct physical interaction between the two is limited at best.[39] A study was completed in more local proximity, examining the diverse bat populations in southeastern Mexico and determining how diverse the viruses they carry could be.[41] However, it became apparent that dromedary camels were the intermediary in the transmission between bats and humans, since camel milk and meat are dietary staples in the Saudi Arabian region.[42] The instances of human-to-human transmission appeared to be isolated to case-patients and anyone in close direct contact with them, as opposed to a broad open-air transmission.[43] By 2017, it was determined that bats are most likely the evolutionary original source for MERS-CoV along with several other coronaviruses, though not all of those types of zoonotic viruses are direct threats to humans like MERS-CoV[44] and "[c]ollectively, these examples demonstrate that the MERS-related coronaviruses are high associated with bats and are geographically widespread."[45]

Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/CFS)

Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/CFS) is a chronic condition characterized by extreme fatigue after exertion that is not relieved by rest and includes other symptoms, such as muscle and joint pain and cognitive dysfunction. In September 2017, the NIH awarded a $9.6 million grant to Columbia University for the "CfS for ME/CFS" intended for the pursuit of basic research and the development of tools to help both physicians and patients effectively monitor the course of the illness.[46] This collaboration effort led by Lipkin includes other institutions, such as the Bateman Horne Center (Lucinda Bateman), Harvard University (Anthony L. Komaroff), Stanford University (Kegan Moneghetti), Sierra Internal Medicine (Daniel Peterson), University of California, Davis (Oliver Fiehn), and Albert Einstein College of Medicine (John Greally), along with private clinicians in New York City.[47]

The team of researchers and clinicians initially collaborated to de-link xenotropic murine leukemia virus-related virus (XMRV) to ME/CFS after the NIH requested research into the conflicting reports between XMRV and ME/CFS. The group "consolidated its vision with support from the Hutchins Family Foundation Chronic Fatigue Initiative (CFI) and a crowd-funding organization, The Microbe Discovery Project, to explore the role of infection and immunity in disease and identify biomarkers for diagnosis through functional genomic, proteomic, and metabolomic discovery."[48] The project will collect a large clinical database and sample repository representing oral, fecal, and blood samples from well-characterized ME/CFS subjects and frequency-matched controls collected nationwide over a period of several years. Additionally, researchers are working with ME/CFS community and advocacy groups as the project progresses.[49]

Acute flaccid myelitis (AFM)

Acute flaccid myelitis (AFM) is a serious condition of the spinal cord with symptoms including rapid onset of arm or leg weakness, decreased reflexes, difficulty moving the eyes, speaking, or swallowing may also occur. Occasionally numbness or pain may be present and complications can include trouble breathing. In August 2019, Lipkin and Dr. Nischay Mishra published a collaborative study with the CDC in analyzing serological data for serum and cerebrospinal fluid (CSF) samples of AFM patients.[50] The Lipkin team utilized high-density peptide arrays (also known as Serochips) to identify antibodies to EV-D68 in those samples. The technology was featured on the Dr. Oz Show in mid-September, illustrating how the enterovirus affects the CSF and the actual Serochip used to do the analysis.[51][52] In October, the University of California, San Francisco published a separate collaborative study with the CDC that confirmed the presence of antibodies to enterovirus in AFM patient CSF samples using phage display (VirScan).[53] "It's always good to see reproducibility. It gives more confidence in the findings for sure," commented Lipkin in an October 2019 CNN article. "This gives us more support of what we found."[54][55][56]

SARS-CoV-2

According to the Financial Times, Lipkin first learnt of COVID-19 from contacts in China, where it first emerged, in mid-December, and in early January he repeatedly urged his Chinese counterparts to publish the virus's genetic sequencing to aid research, and visited senior Chinese officials, including Premier Li Keqiang,[57] to discuss the disease.[58]

On January 29, 2020, Lipkin flew into Guangzhou, China to learn about the outbreak of SARS-CoV-2.[59] Lipkin met with the epidemiologist and pulmonologist Zhong Nanshan,[60] the lead advisor to the Chinese government during the outbreak.[61] Lipkin also worked with the China CDC to access blood samples from across the country for further study into the origin and spread of the virus.[62] Lipkin did not travel to Wuhan, the epicenter of the outbreak, due to fears that this would prevent him from returning to the United States.[63] On returning to the United States, Lipkin self-quarantined for 14 days.[64]Lipkin later contracted SARS-CoV-2 in New York City,[65] refusing to go to hospital and treating himself with hydroxychloroquine at home.[58]

Lipkin criticized what he considered a xenophobic response that blames China for the virus, specifically the words of US president Donald Trump calling it the "China virus" and his decision to suspend funding to the World Health Organization for being "China-centric", calling for "global problems" to be addressed by "global solutions". He said that a series of government missteps helped spread the virus around the world very rapidly, and criticized the US and UK's responses, calling them slow, and blamed insufficient and inadequate testing and tracing for rising fatality numbers. In the US, he singled out as an issue what he saw as an inconsistency in advice, including by president Trump, and highlighted the need for national leadership, while acknowledging states had the ability to make decisions in certain areas. He praised his NIAID superior Anthony Fauci for his integrity. He also warned about the danger of future emergence of new deadly viruses.[58]

After his trip to China, Lipkin maintained links with Lu Jiahai, his research partner at Sun Yat-sen University in Guangzhou, and Zhong Nanshan, to try to establish the origins of the virus.[60] Their efforts, aimed at finding out whether the virus emerged in other parts of China and circulated before it was first discovered in Wuhan in December, include antibody tests of nationwide blood bank samples from pneumonia patients which predate the pandemic, which led to a collaboration with the Chinese Centers for Disease Control and Prevention.[57] According to Lipkin, this research began in early February. The international research team also began studying blood samples from different wild animals which it deemed potential origins of the virus, in order to understand animal-to-human transmission.[57]

Lipkin thinks the virus could have originated in the wild animal trade and undergone “repeated jumps” from animal to human in the weeks before the first cases were logged, such a stream of events having recent precedents in the emergence of MERS-CoV, which jumped from dromedary camels to humans in 2012, and SARS-CoV, from civet cats to humans in 2003.[58]

Lipkin co-authored a paper on The proximal origin of SARS-CoV-2, which was published in Nature Medicine in March 2020.[66]

Views on gain-of-function research

Gain-of-function (GoF) experiments aim to increase the virulence and/or transmissibility of pathogens, in order to better understand them and inform public health preparedness efforts.[67] This includes targeted genetic modification (to create hybrid viruses), the serial passaging of a virus through a host animal (to generate adaptive mutations), and targeted mutagenesis (to introduce mutations).[68] Lipkin is a listed “supporter” of GoF advocate group, Scientists for Science,[69] which was co-founded by Columbia colleague Vincent Racaniello.[70] The US National Institutes of Health placed a moratorium on GoF research in October 2014, and lifted the moratorium in December 2017, after the implementation of stricter controls.[71][72]

Lipkin, while not endorsing every GoF experiment, has said that "[t]here clearly are going to be instances where gain-of-function research is necessary and appropriate." In the example of Ebola, which is incapable of airborne transfer, Lipkin believes that "researchers could make a case for the need to determine how the virus could evolve in nature by engineering a more dangerous version in the lab." Lipkin believes that there should be guidelines in place to govern GoF experiments.[73] Lipkin has called for the World Health Organization to establish strict biocontainment criteria that can be applied globally - including in the developing world - to GoF research.[74]

Selected awards and honors

Year(s)

Award/Honor

Institution/Organization

- 2020 / PRC 70th Anniversary Medal[38] / Chinese Central Government, Central Military Commission, and State Council

- 2016 / China International Science and Technology Cooperation Award[75] / People's Republic of China
- 2015 / Fellow[76] / Infectious Diseases Society of America (IDSA)
- 2010 / Member[77] / Association of American Physicians (AAP)
- 2008 / John Snow Professor of Epidemiology[76] / Columbia University
- 2006 / Fellow[77] / American Society for Microbiology (ASM)
- 2004 / Fellow[77] / New York Academy of Sciences
- 2003 / Special Advisor to the Ministry of Science and Technology[78] / People's Republic of China
- 1986-87 / President, Society of Fellows[79] / Scripps Research Institute

2011-08-28-publichealth-columbia-ed-ian-lipkin-science-to-hollywood.pdf

INFECTIOUS DISEASE Aug. 27 2011

INTERNATIONALLY-RENOWNED "MICROBE HUNTER" WORKED CLOSELY WITH FILMMAKERS TO ENSURE ACCURACY OF STAR-STUDDED SODERBERGH MOVIE ABOUT PANDEMIC.

Oscar-winning director Steven Soderbergh's new movie Contagion imagines a deadly virus outbreak that quickly sweeps around the world. The gripping story is fiction, but the global pandemic it portrays is entirely realistic. Soderbergh and Contagion screenwriter Scott Z. Burns were committed to the truth of the film right from the start and sought out Dr. W. Ian Lipkin, one of the world's foremost microbe hunters and a professor at Columbia University's Mailman School of Public Health, to tap his scientific expertise as they developed the concept.

It wasn't the first time Hollywood had knocked on Dr. Lipkin's door, but it was the first time he said "yes." Lipkin was persuaded that "this was an effort to accurately represent the science and to make a movie that would entertain as well as educate." Now that it is opening in theaters, he hopes that *Contagion* will help people to understand the urgent public health challenges that we face in the 21st century due to increasing international trade and travel, urbanization, loss of wildlife habitats, and inadequate investment in infrastructure for surveillance and vaccine production and distribution.

After early conversations about the movie concept, Lipkin signed on as technical adviser to *Contagion* in March, 2009 and played an active role throughout production. He suggested the movie's plot might be triggered by an outbreak of a virus similar to Nipah, a deadly virus that has, on occasion, migrated from animals to people.

At Columbia, Dr. Lipkin is the director of the Mailman School of Public Health's renowned Center for Infection and Immunity, which does cutting-edge work in microbe detection and discovery. He has identified more than 400 new viruses and was the first to determine that West Nile virus was the cause of the 1999 encephalitis epidemic in New York City.

Some of the scenes in *Contagion* reflect Dr. Lipkin's vivid memories of Beijing when he assisted the World Health Organization and the Chinese Health Ministry manage the SARS outbreak in 2003. At risk on the frontlines of the epidemic, as public health professionals sometimes are, he became ill and was quarantined when he returned to the U.S. On the movie set, Dr. Lipkin shared his experience in China with Matt Damon, offering the actor insight into what it feels like to be behind glass and cut off from loved ons.

Dr. Lipkin also coached *Contagion* actors on the practices and process of scientific research. Kate Winslet and Jennifer Ehle visited the Center for Infection and Immunity to learn the mechanics of being a bench scientist, working with the lab's equipment to do technical procedures. And Elliott Gould, who plays a research scientist named "Ian," talked to Dr. Lipkin about the intellectual process of making a scientific breakthrough. Suggesting to the actor how to look through a microscope and reflect on what it reveals, "I told Elliott it's important that you get this right, because you are playing me," Dr. Lipkin recalls.

The laboratory at the Center for Infection and Immunity, where Dr. Lipkin and his team of 65 conduct their research, also has an invisible role in the movie. In pursuit of authenticity, *Contagion*'s production crew traveled to the lab to record centrifuges whirring, liquid nitrogen hissing, and even the squeaky noise of opening animal cage doors for the film's soundtrack.

In addition to his work at Columbia, Dr. Lipkin co-chairs the National Biosurveillance Advisory Subcommittee (NBAS) of the Centers for Disease Control and Prevention, which was established in response to a Homeland Security Presidential Directive recognizing that infectious diseases are an increasing threat to the nation. From that perspective, Dr. Lipkin hopes that *Contagion* will be a wake-up call for the public that today's fiction could easily become fact tomorrow. He says, "Science is critical to address these challenges. We've been through this with SARS. We will be through it again."

1999 (Sep 26) - NYTimes : "Exotic Virus Is Identified In 3 Deaths"

By Andrew Jacobs / Sept. 26, 1999 / [HN01I9][GDrive]

The mosquito-borne illness that has killed three people in New York City is not St. Louis encephalitis, but a similar disease that has never before been found in the Western Hemisphere, health officials said early this morning.

Scientists in two states who have been examining brain tissue from the people killed by the outbreak of encephalitis confirmed that it was caused either by West Nile virus, from Africa, or Kunjin virus, a variant that is found only in Australia.

Since last month, 14 people in New York City and Westchester County have been diagnosed with encephalitis, although it was unclear whether the two strains identified today are responsible for all the cases.

An official with the Centers for Disease Control and Prevention in Atlanta, and a researcher at the University of California at Irvine said this morning that the closely related strains had been positively identified in the brain matter of New York City residents killed by encephalitis. Until now, neither strain had been found in birds or people in this hemisphere.

[Dr. Duane J. Gubler (born 1939)], director of the C.D.C.'s division of vector-borne infectious diseases, said that the agency's lab found the West Nile virus in the brain of one of the victims early last week. "It was a total surprise to us," he said. "There was no reason to suspect that we'd find West Nile here."

[**Dr. Walter Ian Lipkin (born 1952)**], the director of the Emerging Diseases Laboratory at the University of California at Irvine, said his colleagues had identified the virus in the brains of three victims from Queens that had been sent to his lab last week. "It's very odd that they've been found here," he said. "On the other hand, viruses evolve and they have the capacity to adapt themselves." Dr. Lipkin emphasized that the genetic difference between West Nile virus and Kunjin virus is so slight that the two are practically the same strain.

Until yesterday, New York health officials said they had found the West Nile virus only in birds that had died in and around the Bronx Zoo. But this morning, after the C.D.C confirmed the discovery of the virus in humans, a state official acknowledged that officials had known about the findings of [**Dr. Walter Ian Lipkin (born 1952)**] and Dr. Gubler for several days, but wanted to conduct more tests.

John Signor, a State Health Department spokesman, said the ageny was planning to release the information tomorrow after more testing confirmed the earlier findings. "The identification of a virus is a complex process," he said. "We felt more testing needed to be done."

Despite the discovery that the encephalitis outbreak had been caused by a different virus, officials said that the public health measures undertaken to date would not change: the spraying of mosquitos and warnings to reduce exposure to the insects remains. Mr. Signor said that the treatment for those already infected with the disease would remain the same.

The Federal Centers for Disease Control and Prevention said Friday night that its scientists had identified a West Nile-like virus in four birds from New York that they had tested in their laboratory in Fort Collins, Colo.

The birds included two flamingos and an Asian pheasant from the Bronx Zoo, and a crow reported to be from Scarsdale, said Kristine Smith, a spokeswoman for the New York State Health Department.

Yesterday, city health officials continued collecting dead birds, which they had started to do on Friday. Special telephone lines and asked residents to call in sightings of dead birds. By 4 P.M. yesterday, the City Health Department had received two dozen reports of dead birds in all five boroughs, and sent out staff members from its pest control division to retrieve specimens, said a spokeswoman, Sandra Mullen.

''The birds will be kept on dry ice and brought to our Bureau of Laboratories,'' she said, adding that most of the dead birds reported were crows, which have been dying in large numbers since the beginning of the outbreak. Health officials in Suffolk County collected five dead crows on Friday, and sent them for analysis to the State Department of Environmental Conservation yesterday, said the director of public health, Mahfouz Zaki.

And after receiving reports at 5:30 P.M. on Friday that earlier samples from dead crows tested positive for an encephalitis-like disease, they sprayed South Huntington and Huntington Station with pesticides.

In Manhattan, a team from the Parks Department swept through Central Park on Friday night searching for dead birds but found none, said Parks Commissioner Henry J. Stern. He said that more teams would be dispatched, but that all park staff members had been notified and were on the lookout.

News that the infection was either West Nile virus or an Australian variant has deepened an epidemiological mystery that began in July with the deaths of numerous crows around the Bronx Zoo.

A pathologist at the zoo, [Dr. Tracey S. McNamara (born 1954)], first noticed that large numbers of crows were dying, reaching 40 by August. Then, birds at the zoo, including a guanay cormorant, three Chilean flamingos, a pheasant and a bald eagle, died.

Though the symptoms of both diseases are similar, and the steps to combat them are the same, the mosquitoes that carry them can differ, health officials said.

Ms. Smith of the State Health Department said the mosquitoes that carry St. Louis encephalitis and West Nile viruses, the Culex pipiens, are generally active from dusk to dawn. But another type of mosquito known to carry the West Nile virus, the Aedes vexans, is also active during the day, she said.

The symptoms of both illnesses are usually mild, but in some cases can cause neurological disorders and even death.

Recent advances in nucleic acid diagnostic methods have revolutionized microbiology by facilitating rapid, sensitive microbial surveillance and differential diagnosis of infectious diseases. During his talk at the University of Washington, Dr. W. Ian Lipkin of the Center for Infection and Immunity, Mailman School of Public Health, Columbia University, shares how implementation of these methods may enable intervention when the prognosis is optimal for limiting replication, dissemination, transmission, morbidity and mortality.

The Great AIDS Quest

Editor's note

The performance of the press in reporting the spread of the AIDS plague, one of the most important stories of the century, was abysmal.

No story caught us more ill-equipped or unprepared. The speed with which the disease spread, its enormously complex nature and the scientific ignorance of the press made it a story simply beyond our capabilities.

When the story moved to the search for and ultimate discovery of the cause of the disease, the combination of complexity and ignorance forced reporters into the role of stenographers, mostly unchallenging and unable to scrutinize. As some critics suggest, the story of the discovery of the AIDS virus has not really been reported at all—until today.

This special section of The Chicago Tribune contains that story, an almost book-length account culminating two years of intense work by one of journalism's premier investigative reporters. John Crewdson, 43, won the 1981 Pulitzer Prize for national reporting while a New York Times correspondent and later became metropolitan editor of The Tribune. Now a special national correspondent for The Tribune based in San Francisco, he has been assigned to the AIDS story almost exclusively since it crawled onto the front pages of the newspapers in mid-decade, not because of any special science or medical background but because Crewdson had proven over the years to be precise, cautious, curious and persistent in pursuit of the most difficult and elusive stories.

Twenty months ago, Crewdson was assigned to document how different segments of society, particularly the scientific community, the public health sector and the political establishment, reacted to the AIDS scare.

The resulting account of the quest for the cause of this mysterious and terrible disease is a classic story in many ways.

It is a story of commitment and dedication to mankind and of tireless, often brilliant detective work within the magic and marvelous world of modern medical technology. But it is also a story of cut-throat competition and bare-knuckled politics, of individual ego and national pride, and of the kind of intense pressure on human beings that often brings out the worst in even the best and can result in lying, cheating and outright fraud.

The presentation of this story, an entire special section consisting of more than 50,000 words spread over 16 pages, is extraordinary, to say the least. But the story itself is so extraordinary as to demand it.

As extensive as it is, this account is still far less complete than The Tribune would like, in part because precise scientific explanation can be so exhaustive and, more important, because early in Crewdson's investigation, Dr. Robert Gallo, a key figure, ceased to cooperate. Not only did he decline repeatedly to answer questions, he fought the Freedom of Information requests for public records and made numerous attempts to discredit Crewdson's reporting and impugn his personal integrity, both with his editors and with members of the scientific community.

Still, the story is by far the most complete and detailed look at how the government and scientific communities reacted to this huge and growing public health challenge. And it casts, perhaps for the first time, a brilliant and penetrating light on modern medical science.

James D. Squires

Science under the microscope

1 'We forgot to write the summary'

By John Crewdson

On the afternoon of the day before his 50th birthday, the American scientist Robert C. Gallo sat down at a small desk in a hotel room in Germany. In the chair next to his was Luc Montagnier, one of the French researchers from whom Gallo had been trying for nearly three years to steal the credit for discovering the cause of AIDS.

Neither Montagnier nor Gallo, the unchallenged AIDS superstar at the National Institutes of Health, was there by choice. The two scientists had been forced together by pressure from their governments, and their peers, to write a combined history of their research that would end their increasingly acrimonious dispute.

The Pasteur Institute, where Montagnier works, had formally challenged the patent on the blood test for AIDS developed in Gallo's lab, and the American government was eager to settle the case. Any settlement would turn on the question of who had been first to find the virus that causes the disease and use it to make a test.

The 'definitive scientific history' that emerged from that hotel room in Frankfurt made possible an agreement between the French and American governments, the first ever to resolve an international conflict over a scientific discovery. Officially, the dispute has been settled forever. In reality, the scientific world has been left with more questions than answers about who really discovered the cause of AIDS, and when and where and how.

In an effort to distinguish scientific truth from gossip, rumor and professional jealousy, The Chicago Tribune undertook a reconstruction of the discovery of the AIDS virus that has included the examination of more than 5,000 pages of government documents and interviews with 150 scientists in this country and abroad.

The story that emerges is less heroic than generally portrayed, but no less dramatic: misstated data and secret experiments, phantom viruses and disappearing genes, unreproducible results and muddled lab notes, mislabeled cultures and misleading photographs.

What also emerges is that the history—inelegant, vastly incomplete and technically inaccurate—even begins with a lie. Between the Gallo and Montagnier laboratories, it says, there had always been 'a spirit of scientific cooperation and a free exchange of ideas.'

As with many histories, the biggest lie is in what it doesn't say. Utterly missing from the account of this great scientific achievement is the story of an influential and intimidating scientist who chased the wrong virus for more than a year, only to reverse course and emerge with a virtual genetic twin of the virus that had really been discovered by his rivals in Paris and delivered to him months before.

What happened in Robert Gallo's lab during the winter of 1983-84 is a mystery that may never be entirely solved. But the evidence is compelling that it was either an accident or a theft.

The beginning of the 1980s looked like the beginning of the end for infectious diseases in America. Smallpox had been eradicated, polio was nearly nonexistent and the childhood illnesses were on the ropes. Then, in the spring of 1981, doctors noticed that a few young men in large American cities were dying horrible deaths. Something was ravaging their immune systems, but what?

As the death toll mounted, so did the theories. Because all the early patients were homosexuals, some scientists thought the disease that would later be called AIDS must be a byproduct of the gay lifestyle. But when the same symptoms began turning up in hemophiliacs and in heterosexuals who had received blood transfusions during surgery, the possibilities narrowed. Any number of infectious micro-organisms might be transmitted in semen or blood, but the only thing small enough to evade the filters used to screen the clotting factor given hemophiliacs was a virus.

In May of 1983, less than two years after the first AIDS cases had been recognized by physicians at UCLA, an anxious nation was relieved to learn that scientists at Harvard and the National Institutes of Health had found an important clue. As many researchers had been predicting, it seemed that AIDS was indeed caused by a virus. What came as a surprise was that the virus under suspicion had apparently been around for years.

Its scientific name was human T-cell leukemia virus, HTLV for short, and it belonged to a relatively small group of viruses known as retroviruses. So far HTLV had been linked only to a rare leukemia found mostly in the fishing villages of southern Japan. Now the experts were suggesting it might also be responsible for what would soon become the biggest public health emergency since half a million Americans perished in the great influenza epidemic of 1918.

One of those making the announcement was Robert Charles Gallo, a veteran researcher and laboratory chief at the National Cancer Institute, the biggest and richest of the research institutes that make up the multibillion-dollar federal biomedical complex known as the National Institutes of Health in Bethesda, Md. Not coincidentally, it was in Gallo's laboratory at NIH that the leukemia virus had first been isolated a few years before, a discovery that had propelled Gallo to the top rank of American medicine. Just six months before the announcement, when Gallo was awarded the Lasker prize, the top honor in American biomedicine and frequently a precursor of the Nobel prize, the citation had lauded his "revolutionary discovery of the first retrovirus known to be associated with a human malignancy."

In the summer and fall of 1982, just as the AIDS epidemic was beginning to grip the public's attention, the most important thing on Gallo's mind was finding out how many people around the world had been infected with his new leukemia virus and the even newer substrain, called HTLV-2, that one of his assistants had just isolated from a Seattle seafood salesman.

Arthur Levine, then chief of the cancer institute's pediatrics branch, remembers a conversation with Gallo about AIDS in June of 1982. From colleagues on the West Coast Levine had become aware of the AIDS epidemic early on, and he also knew a thing or two about retroviruses.

"It was a phone call from me to Bob Gallo," recalled Levine, now scientific director of the National Institute of Child Health and Human Development. "I said, 'Bob, have you heard of this bizarre syndrome that's happening in San Francisco and New York?' He hadn't heard of it. I described it to him, and he agreed that it was very intri-

How Tribune AIDS project was reported

Tribune correspondent John Crewdson began this examination of the scientific research on AIDS 20 months ago. Even though he interviewed more than 150 people in this country and abroad, and reviewed thousands of pages of documents, he wasn't able to answer all the questions surrounding the work of Robert Gallo, a key figure in the discovery of the cause of the disease.

The Tribune sought on many occasions to interview Gallo and some of his associates. Gallo answered some questions in a telephone call in September, 1988, but no in-person interview, at which documents could be reviewed and more extensive questions addressed, was ever granted.

In December, 1988, former U.S. Sen. Birch Bayh, Gallo's Washington-based attorney, sent The Tribune a letter stating that "Dr. Gallo is amenable to your interview request and suggests that it should be arranged expeditiously. We assume that your work will not be published until after the interview has taken place." Bayh also asked for a list of questions.

On Dec. 19, a day before the interview was to have taken place, The Tribune delivered 188 questions, to Bayh's office. Three days later, Bayh's office advised The Tribune that Gallo no longer wished to be interviewed.

In January, 1989, in a telephone conversation with Tribune Editor James D. Squires, Gallo said "the lawyers" had advised him not to grant the interview. In the months that followed there were more letters and telephone calls in which Gallo and Bayh complained about questions Crewdson was asking.

Through Squires, The Tribune again tried to obtain an interview with Gallo, agreeing to send Executive Editor Jack Fuller along with, or instead of, Crewdson. On July 28, Squires sent a letter to Bayh with a revised set of questions. There was no response. In October, The Tribune sent another letter noting that the lack of response was being taken to mean no interview would be granted.

Myron T. Essex, a retrovirologist from the Harvard School of Public Health and a longtime Gallo collaborator, declined a request for an interview because of "a heavy travel commitment and a tight schedule."

Another Gallo collaborator, Harvard biologist William Haseltine, also declined a request for an interview.

Gallo's chief molecular biologist, Flossie Wong-Staal, said in a letter to The Tribune that she did not "have the time or inclination to respond to every naive reporter to satisfy his idle curiosities."

Mikulas Popovic, Gallo's former chief virologist, also declined an interview, saying, "This is not the time to write a history. You should wait for 10 or 15 years."

Even outside of science, Robert Gallo is a celebrity

In just five years, Robert Charles Gallo has become one of the most prominent medical scientists in the world. He has won nearly every award his field has to offer—his biography lists nine single-spaced pages worth—and the hundreds of thousands of dollars in prize money that goes with them. He is the only scientist ever to win two Lasker awards, this country's highest biomedical honor. The New York Times calls him a "strong candidate" for a Nobel prize.

Gallo, who heads the National Cancer Institute's Laboratory of Tumor Cell Biology, is also a celebrity outside the realm of science. When the Italian-American Foundation throws its annual awards dinner, he is there with composer Gian Carlo Menotti. When People magazine chooses its "30 Hardest Working Celebs," he makes the list with Dan Rather and British Prime Minister Margaret Thatcher. Last month, Newsweek magazine counted him among America's 25 "leading innovators." Last week he met Pope John Paul II in Rome.

It is a rare news article about AIDS that does not contain Gallo's generously quoted opinion, and an even rarer conference on the disease where he is not a much-sought-after speaker. So much in demand is he by journalists that those attending last year's international AIDS conference in Stockholm were required to enter a lottery for a chance at a five-minute interview.

Gallo has made scientific careers, and those whose careers have become intertwined with his afford him the highest praise. William Blattner, a National Cancer Institute epidemiologist who has spent much of the last decade searching in different populations for the human leukemia virus first isolated in Gallo's lab, says, "Bob is one of the really great scientists of our time."

Dani Bolognesi, the Duke University virologist who followed Gallo into the field of human retroviruses, is often described as Gallo's closest friend. Bolognesi credits Gallo with "a tremendous amount of intelligence, a great deal of intuition. Bob sees through things and over things and around things in ways that are sometimes difficult for us."

Gallo is respected by other researchers less for his scientific acumen than his ability to see the larger picture. "He is able to synthesize," says Wolf Prensky, chief of virology at St. Clare's Hospital in Manhattan. "It's something that few scientists can do well."

"He is imaginative," says Robin Weiss, the noted British retrovirologist. "He doesn't know the literature well, because he's too busy flying around. He's not scholastic in the pedantic, obsessive way that we ought to be. But Gallo comes out with different ways of looking at things."

"I don't have a great analytical talent," Gallo told The Tribune. "I do think, however, I have some talent in thinking originally. And I have some perseverance and I work hard. But I am not dotting all i's and crossing all t's all the time. It has not been my strength. There are far better scientists than me in that line."

Gallo's strong emphasis on personal loyalty, and his legendary temper, are the reasons given most often by those who know him for declining to talk about Gallo on the record. One former associate spoke for many when he said, "If he died, I might talk to you."

Gallo is not unaware that he inspires controversy. "I have friends and enemies everywhere," he says. "I'm not rewarded by scientific peers. There's a lot of people with a lot to gain by certain things, and there's a lot of jealousy. It provides them with an explanation for their own inadequacies. You know what my flaws are; they're obvious. I tend to be aggressive. I tend to be competitive. I hope to God I don't hurt anybody."

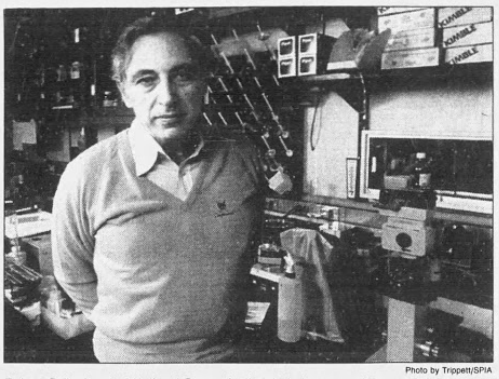

Photo by Trippett/SPIA

Robert Gallo, head of National Cancer Institute's Laboratory of Tumor Cell Biology.

It was Gallo's peers who, until last year, kept him from membership in the National Academy of Sciences, the 2,000-member body that comprises this country's scientific establishment. "He really wanted to be in the academy," says one Nobel laureate. "He would tell you himself that was one of the things that made him unhappy in life."

According to that scientist and others, although Gallo had been proposed for membership several times, on each occasion the selection committee declined to add his name to the ballot. What transpires during academy elections is a closely held secret, but several members confirmed that Gallo finally gained entrance through a process called voluntary nomination in which the selection committee can be bypassed if signatures are obtained from 20 members.

Academy memberships are a plum, but it is the gleaming gold disc with the bas-relief of Alfred Nobel that to a large degree drives science forward. "I don't know if I'll ever get it," Gallo told The Tribune. But he notes that three out of four Lasker recipients have gone on to win the Nobel, including this year's winners, J. Michael Bishop and Harold Varmus of the University of California, both of whom also shared the Lasker prize with Gallo in 1981.

Gallo suggests his two Laskers "ought to mean something" to his chances, and he adds that "the president of the University of Chicago, Leon Jacobsen, has more than once nominated me for a Nobel prize."

Jacobsen, an emeritus professor of medicine at Chicago, where Gallo served his internship and residency in the 1960s, has never been the university's president, and he will not discuss having placed Gallo's name in nomination. "People just don't talk to each other about those things," he says. But Jacobsen does volunteer that he helped engineer Gallo's admission to the National Academy of Sciences.

"We had a hell of a time getting him in," Jacobsen says, "because people are jealous of him. He's published 600 or 700 papers, and he runs a big show. I talked to a lot of these people who are against him, not because of his work but just on principal, whether he was doing too much or publishing too many papers. You know, these things get on some people's nerves, I guess, because maybe they'll put out one a year and he puts out 50."

Gallo's curriculum vitae, nearly a half-inch thick, contains more than 700 scientific articles—a prodigious number even for a scientific superstar. In the last three years alone, Gallo has been a coauthor on more than twice as many articles as any of the other leading scientists in his field. He has not done any scientific "bench work" in years, but in listing himself as an author on most of the papers published by other researchers in his lab, Gallo is hardly alone among the heads of major laboratories.

Several of the articles that bear his name also describe experiments done in other laboratories in which he and his staff played no direct part except perhaps to provide a snippet of DNA or some other piece of raw material. But engineering such collaborations is one of the things Gallo does best. "To be a success in science these days you need a different sort of talent than just the ability to be a good experimenter or ask the right questions," says another cancer institute scientist. "It's become an entrepreneurial business, and Gallo's good at that. He was one of the first of the big-time laboratory operators."

Gallo's laboratory, atop Building 37, a modern concrete-and-glass tower on the edge of the university-style campus of the National Institutes of Health in Bethesda, is the unabashed envy of his colleagues. So is his $8 million annual budget, an enormous sum even for a scientific laboratory that employs more than 50 researchers and support personnel. So is his devoted permanent staff, some of whom have been with him for a decade or more. "It's a very personal operation," says a cancer institute colleague. "That's what everybody wants, to be surrounded by people who will bust their backs to make you look good."

The quality of Gallo's staff is bound to be diminished by the departures of two of his top researchers. Mikulas Popovic, his chief virologist, who played a central role in the isolation of the AIDS virus, left in August for a job at New Mexico State University. Gallo's chief molecular biologist, Flossie Wong-Staal, is said to be leaving Bethesda in January for San Diego.

Each year for the past several years, Gallo has hinted to his friends that he, too, is on the verge of leaving the cancer institute for academia or private industry. At different times he has been rumored to be in negotiations with Duke, Johns Hopkins and Yale and, most recently, with the British financier Robert Maxwell.

The possibility that Gallo might move to Yale was seen by friends as particularly significant in light of his frequently quoted remark a few years back that, because he had attended a lesser-known medical college, he felt the need to work all the harder to prove himself.

Gallo, 52, the only son of a comfortably well-off family, grew up in Waterbury, Conn., where his late father, a metallurgist, owned a small but successful company. Gallo has often said it was the death of his younger sister, Judith, from childhood leukemia that inspired his interest in medical research. After graduating summa cum laude with a degree in biology from Providence College in Rhode Island, he won a medical degree from Philadelphia's Thomas Jefferson University.

In 1965, following his internship and residency at the University of Chicago, Gallo joined the National Cancer Institute as a clinical associate. But after a year of treating cancer patients, an experience he has described as unsettling, he joined the institute's research arm and began a rapid advancement through the ranks, gaining his current position as laboratory chief in 1972.

The rumors of Gallo's departure come and go but Gallo remains at NIH, and those who know him well believe he will never leave. "He never can get a set-up like he's got there now," one friend says, and the cancer institute is happy to see him stay. "In biological research I don't think a supreme personality reigns," says another scientist. "There's no Einstein. He's the only star the NIH has left. He's their big hope for a Nobel prize."

Money and prizes aside, nowhere else will Gallo be able to match the influence he enjoys among those at NIH whose policies determine the course of biomedical research in this country and, to a large extent, the rest of the world. For years, Gallo's position at the cancer institute as first among equals derived from his close personal relationship with the institute's longtime director, Vincent T. DeVita Jr., who resigned unexpectedly last fall to take the No. 2 job at Manhattan's Memorial-Sloan Kettering Cancer Center.

"DeVita and Gallo were very close," says one doctor who knows both men well, and after DeVita's resignation there were fresh rumors that Gallo would not be far behind. But the rumors ceased when DeVita was replaced by Samuel Broder, who worked closely with Gallo during the early years of AIDS research. A former NCI official predicts that "with Broder there, Gallo will still get everything he needs," and Broder's praise of Gallo is unrestrained.

"Gallo is one of the paradigmatic figures of the 20th Century," Broder told the Washington Post. "He's influenced things in our daily lives to an incalculable degree. Einstein, Freud—I'd put him on a list like that, I really would."

In right place at right time, three French scientists make history

When Luc Montagnier arrives for work at the Pasteur Institute, it's not uncommon for him to find someone with AIDS waiting outside his lab. The reason is always the same: the hope that somehow the scientist who discovered the virus that causes the disease will know how to cure it. "These poor AIDS patients," Montagnier says with a shake of his head, "they regard me as a god, you see."

Although Montagnier's work with AIDS has brought him an international reputation, he is regarded as less than a god by his colleagues at the Pasteur. Earlier, his most noteworthy achievement came in the mid-1960s; as a young scientist in London, he developed a method for growing animal cancer viruses that is still widely used.

Last year, when Montagnier offered himself as a candidate for the Pasteur's directorship, a position filled by a vote of the faculty, he reportedly lost by a large margin. Now he is "in discussions" with financial backers in California who want him to head a new research institute in La Jolla that will be devoted to the search for an effective treatment for AIDS.

"My motivation comes back to the patient," Montagnier says. Although he would like to oversee the La Jolla institute while keeping his position in Paris, he acknowledges that might not be possible. "As I view it now I won't be leaving Pasteur," he says. "But if I'm forced to leave I will leave, of course."

Montagnier, 57, grew up in a small town south of the Loire Valley during the World War II. "My father was an accountant," he says. "It was the dream of my parents that I should become a doctor. It was the first time in my family somebody went to college. But I decided I should study not only medicine but also science. I was more interested in science."

Jean-Claude Chermann also began his education with the idea of becoming a doctor. "I came from a very poor family," he says. "My parents were divorced since I was 4 years old. My mother was a seamstress, and at night she was an usher in the theater. I did not want to be a scientist. I would like to be a physician, a surgeon. But I have to work for paying my study and so on, and I decided that it was too long to make physician."

Chermann had been at the Pasteur only a few years when, in the early 1970s, he was approached by a friend of a friend, a young student named Francoise Barre. The only child of a middle-class Parisian family, Barre had played with microscopes and chemistry sets. "I was always interested in the mechanisms involved in human life," she recalls.

As a University of Paris undergraduate, Barre eventually faced the same decision as Montagnier and Chermann, whether to become a doctor or to go into pure science. Hoping hands-on experience would help her decide, she asked Chermann for a job in his lab. After she graduated the job became full time. In 1975, when Chermann elected to work on retroviruses rather than antiviral drugs, Barre remained at his side.

Chermann's decision would irrevocably alter the course of both their careers and their lives. In late 1982, Montagnier, by then the Pasteur's chief of viral oncology, was asked by a group of Paris physicians to look for a retrovirus in patients suffering from a new disease of the immune system. Chermann and Barre were the only other scientists in his unit experienced in isolating and growing retroviruses. Within a few weeks, Montagnier, Chermann and Barre had discovered the virus that causes AIDS.

Glossary

AMINO ACIDS: the building blocks of **proteins**. Although there are hundreds of amino acids, only 20 are ordinarily found in proteins.

ANTIBODIES: Protein chains produced by the immune system that bind to, and often neutralize, **viruses** and other invaders. Viral antibodies are a sign that the virus is, or has been, present.

ATLV: Adult T-cell leukemia virus, the name given by Japanese scientists to the virus that they discovered, which is the same as Robert Gallo's **HTLV-1**.

B-CELL: The immune system cell involved in producing **antibodies**. A line of cancerous B-cells, called BJAB, was used by the French to grow the AIDS virus called **LAV**.

DNA: Deoxyribonucleic acid; long chains of chemical compounds called **nucleotides** that contain genetic code for assembling proteins. The DNA containing the genetic code for the AIDS virus has about 9,200 nucleotides. By contrast, the DNA code for a human being has about 3 billion nucleotides.

ENZYME: Biochemically active **protein** that regulates viral and other biochemical activities. The enzyme the AIDS virus uses to reproduce itself is called **reverse transcriptase**.

H9: a permanent line of **T-cells** created in Gallo's lab by cloning a single T-cell from an established T-cell line called **HUT78**. When the H9 cells began to multiply, they were infected with the pooled AIDS virus that became known as **HTLV-3B**.

HIV: Human immunodeficiency virus, the generic name for the virus that most scientists believe causes AIDS.

HTLVA: The name given to what may have been an AIDS virus isolate used in experiments in Robert Gallo's lab in early 1984. The derivation of the term is unclear because the existence of such a virus was never publicly acknowledged.

HTLV-1: Human T-cell leukemia virus isolated in Gallo's lab. The first retrovirus associated with cancer in humans, it infects **helper T-cells** and causes them to proliferate wildly. Japanese scientists established a connection between HTLV-1 and adult T-cell leukemia.

HTLV-2: Variant of **HTLV-1**, also isolated in Gallo's lab. HTLV-2 was found in 1981 in a patient code-named MO. It has since been discovered in fewer than a half-dozen patients with an extremely rare disease called hairy cell T-cell leukemia, but scientists are unsure whether the virus is the cause of the disease.

HTLV-3: Gallo's original name for the human retrovirus that causes AIDS. The name was later changed to **HIV** after it became clear the AIDS virus was not related to **HTLV-1** and **HTLV-2**.

HTLV-3B: Gallo's principal AIDS virus isolate, reportedly obtained by pooling tissue culture fluids from 10 individuals in the **H9** T-cell line. Several distinct AIDS virus **DNAs** have been cloned from HTLV-3B that are genetically indistinguishable from the French AIDS virus called **LAV-1**.

HUT78: Human **T-cell** line established in the late 1970s by NCI researcher Adi Gazdar. The progenitor of the Gallo cell line called **H9**, HUT78 was also used in Gallo's lab to grow the French AIDS virus called **LAV-1**.

AIDS

Continued from page 1

guing. And then I said the most intriguing thing is that I think the cause of this syndrome is going to be a retrovirus related to HTLV. He said that's very interesting and got off the phone."

The "bizarre syndrome" was being watched most closely by the federal Centers for Disease Control in Atlanta, where a small group of researchers was hunting frantically for its cause. In the fall of 1982, it occurred to a young CDC virologist named Cy Cabradilla, who had done his postdoctoral fellowship at the cancer institute a few years before, that one of Gallo's two human retroviruses might have something to do with AIDS.

"We were looking at every virus we could get our hands on to see if there was any relatedness," Cabradilla said. "The only one we hadn't really looked at was the human retrovirus. I made an appointment to go up and talk to Bob about evaluating some blood samples for us against HTLV. I spent an afternoon up there. He didn't seem that interested. I don't think he wanted to get involved with a gay disease. I think what turned him around was Max."

"Max" was Myron T. Essex, one of Gallo's longtime collaborators and a senior researcher at the Harvard School of Public Health. Using an established laboratory technique called an immune fluorescence assay, Essex had been testing blood samples from young homosexual men with this newly reported wasting disease.

In the Essex test, the patient samples were exposed to cultures of white blood cells that were known to be infected with the leukemia virus. If the blood contained antibodies to the virus—antibodies are proteins manufactured by the immune system to neutralize invading viruses and other microbes—they would presumably stick to the virus in the cells. When the cells were examined under an ultraviolet light, those to which antibodies had become attached would glow with an iridescent sheen.

Essex was finding that impressive percentages of the samples were positive, an indication that the AIDS patients were infected with the leukemia virus. According to Essex, however, his test was not picking up antibodies to the leukemia virus itself but to a mysterious new protein that seemed to appear on the outer surface of the virus-infected cells as a product of the process of infection.

Essex's data were hardly conclusive, but they were tantalizing nonetheless. As one member of Gallo's staff recalled later, when Gallo first heard about what was going on in Essex's lab at Harvard, "it was like Christmas." For Gallo, the idea that his obscure leukemia virus might be the cause of AIDS made a certain amount of scientific sense.

For one thing, the leukemia virus infected a particular kind of white blood cell known as a helper T-cell, and it was a shortage of helper T-cells that was apparently causing AIDS patients to fall ill with various exotic diseases by robbing their immune systems of the ability to respond to infection. For another, the leukemia virus was a retrovirus, and there was evidence that an animal retrovirus, feline leukemia virus, could cause the same kind of immune deficiency in house cats.

Because so many AIDS patients were homosexual men, many scientists assumed that whatever was causing the disease was transmitted sexually—and so, they thought, was HTLV.

But even if Essex was right, finding antibodies to a protein on the surface of leukemic T-cells was like finding the footprint outside the window after the burglar had fled. Gallo wanted to catch the burglar in the act by finding AIDS patients who were infected with the leukemia virus itself.

From doctors and hospitals around the world, blood and tissue cells from patients with AIDS or pre-AIDS, the collection of lesser symptoms that often precede the disease, had begun arriving in cartons of dry ice at Gallo's laboratory on the top floor of Building 37 on the NIH campus. After the samples were logged in they were tested for reverse transcriptase, the enzyme that retroviruses manufacture in order to reproduce themselves. Those that tested positive were examined for evidence that Gallo's leukemia virus was present in their cells.

The early results were encouraging. Within weeks, Gallo's assistants had detected the leukemia virus in the white blood cells of two East Coast homosexuals, a young Haitian woman named Marcellin who had died of AIDS in Paris, and a 31-year-old Frenchman named Claude Chardon who had been given a blood transfusion in Haiti after losing his left arm in a motorcycle accident.

Including the two East Coast homosexuals and Marcellin, nearly all of those outside Japan in whom the leukemia virus had been found were black. Daniel Catovsky, a researcher at London's Hammersmith Hospital, had discovered it recently in several Caribbean immigrants there, and some scientists were beginning to wonder whether blacks were somehow genetically predisposed to infection with HTLV-1. Most of the infected blacks didn't have AIDS. On the other hand, nearly all of those who were sick with AIDS were both white and homosexual. Chardon seemed to represent some kind of bridge. He wasn't black, and according to his widow he wasn't gay. If Chardon had the leukemia virus and he also had AIDS, then perhaps the two really were connected.

The cells from Marcellin and Chardon had been brought to Gallo in February of 1983 from Paris by a French immunologist named Jacques Leibowitch. When Leibowitch heard about Chardon's case from doctors at the Saint-Lazare Hospital in Paris, he had been quick to recognize its significance. "I was there at the seminar where they presented the case," the Harvard-trained Leibowitch recalled, "and I was strongly motivated to get the cells of this guy. It could serve the purpose of demonstrating that the cause of AIDS was not homosexually related."

In early March of 1983, Gallo sent a paper reporting the detection of his leukemia virus in the two East Coast homosexuals to Science magazine, a weekly published by the American Association for the Advancement of Science and second only to the British journal Nature as a prestigious forum for biomedical research. In a cover letter to the magazine's editors, Gallo made clear he was not claiming the leukemia virus caused AIDS. Rather, he hoped his findings might "direct research in AIDS toward a class of agents not addressed in the literature to this point."

Within a few weeks Gallo had sent Science a second paper, this one reporting that the leukemia virus had now actually been isolated from one of the two East Coast homosexuals and had also been detected in the cells of Marcellin and Claude Chardon. In the meantime Essex had submitted a paper of his own to Science, reporting that up to 40 percent of the AIDS patients whose blood he had tested had antibodies to the mysterious protein on the surface of leukemic helper T-cells. Harvard University, which like most universities owns its faculty members' inventions, promptly applied for a patent on the Essex test.

A few weeks before publication of the papers, Gallo presented his superiors at the National Cancer Institute with a bold proposal. The NCI, he wrote, should move quickly to take the lead in what seemed likely to become a fierce scientific and medical battle against AIDS. A special AIDS working group was needed, Gallo said, and he suggested that he be named its chief of research, an additional responsibility that would require more laboratory space and personnel, but only "until the problem is solved or [for] three years, whichever comes first."

When the papers from Gallo and Essex appeared in the same issue of Science in May of 1983, they made a considerable splash. The Washington Post called the possible involvement of Gallo's leukemia virus "the strongest clue yet to the cause of AIDS." The Boston Globe nominated the virus as "the leading suspect for causing the illness." Even Science's archrival, Nature, took note of "an important group of papers" that "confirms that HTLV is indeed somehow linked with AIDS."

More than 1,200 Americans were already sick with AIDS. Physicians in San Francisco, New York and other big cities were seeing new patients each week, and they were becoming increasingly anxious to know more about the mysterious and deadly disease with which they were confronted. Now they were being told that AIDS might be caused by a leukemia virus. To some, the idea that a cancer virus might underlie an immune deficiency didn't make immediate sense, but most of those who read the articles in Science put their confusion down to lapses in their own understanding of retroviruses and AIDS. The relatively small number of scientists who knew something about retroviruses did have some questions, however.

The curious thing about Essex's data, they thought, was that his numbers were neither high nor low—not high enough to show a conclusive link between the leukemia virus and AIDS and not low enough to be a coincidence. But Gallo and Essex agreed that Essex's test needed to be refined, and they had answers for the other objections as well. When it was pointed out that there was no AIDS in southwestern Japan, where the leukemia virus was most common, Gallo suggested that maybe AIDS hadn't been noticed there yet, or that Japanese people perhaps responded differently to the disease.

The news accounts about the possible link between HTLV and AIDS—and there were many in the spring and summer of 1983—barely mentioned a fourth paper in the same issue of Science. The lapse was perhaps understandable since the magazine itself, in an accompanying news article, had dispensed with the paper in a single sentence. When the nonscientific press referred to the paper at all, it was mostly as an afterthought, to note that researchers at the Pasteur Institute in Paris had provided confirmation of the findings by Gallo and Essex.

The origins of the AIDS work in Paris traced back to the end of 1981, when a group of physicians began meeting informally to discuss what one member, a young immunologist named David Klatzmann, called "a disease which at that time interested nobody." Jacques Leibowitch was also a part of the Paris group, and it was he who focused the group's attention on the possibility that a retrovirus was responsible for AIDS.

"None of us was a retrovirologist and we had no idea what this virus was," Klatzmann recalled. "We discussed how to isolate such a virus, and we reasoned that maybe the lymph node was the best point to look at." Another member, Francoise Brun-Vezinet, had taken a course in virology at the Pasteur Institute and remembered the name of one of her lecturers. In mid-December of 1982 Brun-Vezinet put in a call to Luc Montagnier, the chief of the Pasteur's department of viral oncology. Yes, Montagnier said, he had heard about AIDS and had thought about the possibility that a retrovirus was involved. If the clinicians would bring him a lymph node from someone with AIDS, he would look for such a virus.

The French physicians had already decided the best place to look was the cells of someone who did not yet have full-fledged AIDS. If a virus was present, and if the virus was infecting the helper T-cells, then a person in whom the disease was not so advanced might have more infected cells in which to find the virus. As it happened, another of the Paris clinicians, a tropical disease specialist at the Claude Bernard Hospital named Willy Rozenbaum, had been seeing just such a patient, a young homosexual named Frederic Brugiere.

A fashion designer, Brugiere had been suffering for several months from the persistently swollen lymph glands that often precede AIDS. Other than that, however, he was healthy. On the afternoon of Jan. 4, 1983, Francoise Brun-Vezinet delivered a slice of Brugiere's lymph node to Jean-Claude Chermann, who worked under Montagnier as a lab chief at the Pasteur. Chermann gave the sample to Montagnier, who minced the tissue and put the T-cells he extracted into a flask filled with nutrients to keep them alive. To encourage the growth of any virus that might be present in the cells, Montagnier added an antibody designed to counter the effects of interferon, a protein produced by the immune system that protects T-cells against viral infections.

Because the flask was stored in an incubator that kept it at body temperature, if a virus was present it should begin reproducing in the laboratory just as it would in Brugiere's body. If it happened to be a retrovirus, the first evidence of its existence would be the activation of an enzyme called reverse transcriptase as it assembled DNA copies of the virus's native RNA.

In one sense, the AIDS epidemic could not have come at a better time. If AIDS had appeared even a decade earlier, researchers would not have known where to begin searching for its cause. Helper T-cells had not yet been recognized as a separate class of white blood cells, retroviruses in humans were unknown and there were no reliable tests for reverse transcriptase. Now, however, there was such a test. Every three days Montagnier drained fluid from the culture and gave it to Francoise Barre, another Pasteur scientist who worked for Chermann and who was skilled at using radioactive isotopes to measure the amount of DNA being synthesized by a retrovirus.

Seven times, at three-day intervals, Barre tested the culture fluids for reverse transcriptase, and seven times the results were negative. But on Jan. 26, 1983, when the radioactivity in the fluids reached 5,600 counts per minute—about three times the background radiation at the Pasteur—Barre began paying attention. Three days later, when the radiation level reached 22,000, it seemed only one conclusion was possible: a retrovirus was growing in Frederic Brugiere's cells. Then the numbers on the radiation meter began to fall.

"The first reaction was to think that we had tissue culture problems," Barre recalled, and such a conclusion was understandable. When Gallo's leukemia virus, then the only known human retrovirus, was growing in a culture, the reverse transcriptase level didn't rise and fall; it simply continued to rise as the virus transformed increasing numbers of white blood cells into cancer cells. But the cells in the French AIDS virus culture weren't multiplying as they would have in the body of a cancer patient; they were dying.

If AIDS was characterized by a decline in the number of helper T-cells, and if a virus was infecting those same cells, then perhaps there was nothing wrong with the culture medium after all. Perhaps it was the virus that was killing the cells. That would explain not only the decline in reverse transcriptase activity and the dying cells, it would also explain the clinical progression of AIDS.

The Pasteur group's solution to the question of how to keep the virus growing was both simple and elegant. "We decided," Barre says, "to add fresh cells." When a second attempt was made to grow the virus, Brugiere's cells were mixed with fresh T-cells from blood recently donated by a Spanish tourist at the Pasteur's hospital. There was nothing special about the Spaniard. "I was in a hurry," Montagnier recalled. "The first donor who came along was the right one."

When the new culture was tested for reverse transcriptase on Feb. 14, the results were negative, and they were still negative on the 17th, the 20th and the 22d. But on Feb. 27, the radiation level began to climb, and on March 1 it peaked at 14,000. Three days later it began to fall, but this time there was no concern about possible tissue culture problems. Indeed, the excitement in the Pasteur's small AIDS group was palpable. But just to be sure, the group wanted to reproduce the same result one more time. From Montagnier's crowded lab, the culture was moved to its own room, across the hall from Barre's office on the first floor of one of the Pasteur's oldest buildings.

Because the Spaniard had gone back to Spain, when Barre and Chermann in-

Antibodies: Weapons that target specific intruders

The human immune system fights disease with many weapons. Among the most formidable are antibodies, the biochemical medicine the body uses to cure everything from influenza to pneumonia—and, once cured, to protect itself against a recurrence.

Anything that is not a natural constituent of the body—anything "foreign"—may elicit an immune response, including the production of antibodies that are specifically designed to neutralize the invader. When a patient's body "rejects" an organ that has been transplanted from someone else, it is because the patient's immune system has recognized the heart or liver as something foreign.

In cases of infectious disease the foreign invader is often a virus, a particle a few millionths of an inch in diameter constructed primarily of proteins. As soon as the presence of a virus is noted by the immune system's sentinel cells, a biochemical message is passed to other cells that an invasion is underway.

Like a locksmith who fabricates a key from a wax impression of a lock, the immune system's complex machinery assembles a set of antibodies that have a unique biochemical attraction to the proteins of the invading virus.

When an antibody molecule recognizes a passing virus particle in the patient's bloodstream or tissue, it attaches itself to the virus and renders it harmless. If the person is otherwise healthy and his immune system is functioning properly, he will usually recover after all the virus particles have been neutralized. And because the immune system "remembers" the biochemical makeup of each invading virus, any future attack will be met with such a rapid immune response that the patient will probably never again experience any symptoms of disease.

The vaccines that protect against viral diseases like measles and polio are made with altered versions of the viruses that, although altered, still trigger the production of protective antibodies.

Whether there will ever be an effective vaccine for AIDS is still an open question. Although antibodies to the AIDS virus usually appear within several months of the initial infection, they almost always fail to eradicate the virus; there are only a few cases on record of patients who are antibody-positive and virus-negative, suggesting that the AIDS virus may have been eliminated by their immune systems.

Precisely why the immune response to AIDS is so ineffective is not yet fully understood, although it probably has something to do with the fact that during the first several years of infection the AIDS virus lies quiescent inside the very cells that control the patient's immune system—the helper T-cells—and also with the degree to which the AIDS virus alters its genetic makeup as it replicates inside the patient's body.

When the AIDS virus finally does begin to replicate, it destroys the ability of the T-cells to perform their protective function. With his immune system gravely impaired, the AIDS patient eventually dies of some otherwise nonfatal disease against which his body could no longer mount a defense. Because of the absence of T-cells and their inability to generate antibodies in the later stages of AIDS, patients who are seriously ill often test negative for antibodies to the AIDS virus.

LAV: Lymphadenopathy-associated virus, the name originally given by scientists at the Pasteur Institute to the AIDS virus they discovered in 1983. The original French isolate, found in T-cells from Frederic Brugiere, the patient known as BRU, was called **LAV-1**. Like **HTLV-3B**, LAV-1 contains several distinct AIDS virus DNAs, at least two of which are genetically indistinguishable from variants cloned from Gallo's HTLV-3B.

LENTIVIRUS: A class of slow-acting **retroviruses** including the AIDS virus. Before AIDS, lenti-retroviruses had been found only in animals.

LEUKEMIA: Cancer marked by the uncontrolled proliferation of white blood cells which can take several different forms depending on which cells have become cancerous. Cancers of lymphocytes such as T- and B-cells outside the blood are lymphomas.

MOV: The name used in Gallo's lab for an AIDS virus isolate in late 1983 and 1984. The initials apparently stand for "MO Variant," stemming from the belief among Gallo's assistants that the AIDS virus was genetically similar to HTLV-2. What became of MOV is unclear, because its existence was never publicly disclosed.

NUCLEOTIDES: Chemical building blocks of **DNA** and **RNA**. DNA is composed of four nucleotides: adenine, guanine, thymine and cytosine. RNA substitutes uracil for thymine.

PROTEINS: Chains of **amino acids** varying greatly in size and shape. **Enzymes** and hormones are biochemically active proteins. The AIDS virus has several structural and regulatory proteins including its main core protein, called p-24, and its envelope protein, gp120. The numbers refer to approximate molecular weights (in thousands).

RETROVIRUS: Virus whose genetic code is written in **RNA** rather than **DNA**. Retroviruses reproduce by using **reverse transcriptase** to copy RNA into DNA.

REVERSE TRANSCRIPTASE: The enzyme **retroviruses** manufacture to enable them to reproduce inside a host cell.

RNA: Ribonucleic acid; single-stranded chain of **nucleotides** that contains the genetic code for some viruses, including **retroviruses**. Various forms of RNA also assemble **proteins** according to instructions contained in **DNA**.

SERUM: The pale yellow fluid left over after the cells have been removed from blood. It is used for testing for viral antibodies.

T-CELLS: The "controllers" of the human immune system. **Helper T-cells**, also known as T-4 cells, direct the production of **antibodies** by **B-cells**. Suppressor T-cells signal the immune system to "stand down" after a virus or other invader has been vanquished.

TI7.4: Human **T-cell** line established at M.D. Anderson Hospital in Houston. Along with **HUT78**, it was used in Gallo's lab to grow the French AIDS virus called **LAV-1**.

VIRUS: Infectious organism consisting of nucleic acid, either **DNA** or **RNA**, and **proteins**, sometimes contained in protective envelope of fatty material. Some viruses are harmless; others cause disease by damaging the cells they infect.

WHITE BLOOD CELL: Immune system cells that circulate in the blood and of which there are several types, including the lymphocytes called **T-cells** and **B-cells**.

Continued from preceding page

fected the culture for a third time they used T-cells from umbilical cord blood supplied by a nearby maternity hospital. Cord blood cells, as they are called, are among the most susceptible to infection by a virus because the newborn babies from which they come are mostly virus-free. On March 14, when the reverse transcriptase level again reached 14,000, two important conclusions were unavoidable: "First, that the virus was killing the cells," Chermann said. "And secondly, that we have to add fresh cells to keep the virus growing. That was the most important thing."

Besides the presence of reverse transcriptase, there were other indications the Pasteur group had found a retrovirus. Tests showed that the virus's genetic material was RNA rather than DNA, and also that the virus particles were the right size and density for a retrovirus. When some of the infected cells were placed under an electron microscope, which uses beams of electrons rather than rays of light to "see" exceedingly tiny things, the resulting photographs showed what looked like retroviral particles budding from the surface of an infected T-cell.

But which retrovirus was it—Gallo's leukemia virus or a new human retrovirus altogether? The photographs were indistinct, but Chermann and Barre didn't see how it could be the leukemia virus. That virus made T-cells multiply rapidly, and this one was killing them.

In February of 1983 Montagnier called Gallo to say the Pasteur group had found what looked like a new retrovirus in an AIDS patient in Paris. Whether it was Gallo's leukemia virus or not wasn't clear, but if Gallo would send the French some antibodies to the leukemia virus they could find out. The request piqued Gallo's curiosity about what was happening on the other side of the Atlantic. "He was very interested," Barre recalled. "He told us that he also had some data indicating that HTLV could be involved in this disease."

The antibodies Gallo sent to Paris were designed to recognize the two main proteins that form the core of the leukemia virus. If they reacted with the virus growing in the Pasteur's culture, then it must be the leukemia virus. But when the antibodies were added to the culture, there was no reaction at all. "It was for us," says Chermann, "the first proof that the virus was different."

In early April, Montagnier informed Gallo that the antibody tests had been negative and that the French now believed they had found a new human retrovirus related to AIDS. "I said we were close to writing a paper," Montagnier recalled. "He said you have to hurry because we also have written some papers [and] Essex also has done it, and perhaps we could have all the papers in the same issue of Science."

Over a weekend, Montagnier and Barre, whose English was more fluent than Chermann's, hammered out a manuscript reporting the isolation of their new retrovirus from Frederic Brugiere, who would henceforth be known in the scientific literature as BRU. Listed first among the authors, the position traditionally reserved for the researcher who has made the greatest contribution to the work, was Francoise Barre. Chermann's name was second, followed by Brun-Vezinet and Rozenbaum. As the senior scientist in the group, Montagnier was last.

The French paper took careful account of the differences between the virus isolated from BRU and Gallo's leukemia virus. There hadn't been any reaction between their virus and the leukemia virus antibodies. Nor had any of the antibodies in BRU's blood reacted with the leukemia virus, which meant that BRU wasn't infected with HTLV-1. The two viruses, the paper concluded cautiously, were "not immunologically related," and the rest of the article was just as carefully worded. The French would have been rash to claim their virus was the cause of AIDS, and they didn't. Its role in the disease, they said, "remains to be determined." Still, the evidence suggested that they had found something new.

Rather than consign such an important article to the mail, Montagnier handed the finished manuscript to his technician, Jacqueline Gruest, who was on the way to visit her daughter in Washington, D.C. But instead of asking her to deliver it directly to Science, he told her to take it to Gallo in suburban Bethesda.

As with most major scientific journals, papers that are to appear in Science are subjected to peer review, an anonymous evaluation of their strengths and weaknesses by other experts in the same field. While a positive review does not ensure publication, a negative review usually means a paper will be rejected. Unlike any other major journal, however, Science allows its prospective authors to suggest their own reviewers, and when Gallo volunteered to review the paper Montagnier quickly agreed.

Once he had the paper in hand, Gallo noticed that the French had neglected to write an abstract, the long summary paragraph that precedes most scientific papers and other scholarly articles, and the absence of an abstract was more than a minor omission. The abstract is as much as many readers of scientific journals are willing to digest. Moreover, it is the only part of a paper reproduced in the electronic databases that are now the most common tools of bibliographic research. Gallo, however, stood ready to help. "Gallo called me," Montagnier said, "and since the time was very short he said to me that he should write the summary."

On April 19, 1983, Gallo sent the Pasteur paper to the editors of Science with a strong letter of recommendation signed by himself and two of his top assistants. "This paper," the three reviewers agreed, "is of obvious immediate great importance and relevance. It will be of very great interest to virtually all scientists and clinicians. The work is careful. The discussion is clear and well-thought-out. It should be published as rapidly as possible." Gallo also included his abstract with the manuscript, but his summary of the French research made it sound as though the virus in BRU's lymph nodes was either the Gallo leukemia virus or a very close relative.

The abstract began by calling the French virus a C-type retrovirus, the same class of retrovirus to which the leukemia virus belongs. It also said that the protein at the core of the French virus was similar to the core protein of the leukemia virus, and that antibodies in BRU's blood had reacted with some of the leukemia virus's proteins. Gallo had also added a sentence to the text of the paper itself. "The virus," he wrote, "appears to be a member of the human T-cell leukemia virus (HTLV) family."

Montagnier remembers being "confused on the phone" as Gallo read the French his abstract, and Barre recalls that "it was very difficult by phone to object" because "you cannot read, you just hear." Only when they saw the abstract later did the Pasteur group realize it didn't accurately reflect the conclusions in their paper.

The French hadn't determined, for example, whether their virus was a C-type or not. "I was very cautious," Montagnier recalled. "I was not saying it was something different from a C-type." Montagnier was also distressed by Gallo's description of the core proteins of the two viruses as similar. "I would not ever agree to that," he says now, "because we showed no cross-reaction" between the French virus and Gallo's antibodies. "This was misleading. The core proteins did not cross-react."

Nor was there any evidence in the French paper to support Gallo's assertion in the abstract that antibodies in BRU's blood had reacted with the proteins of the leukemia virus itself. The French had seen a reaction between BRU's blood and something on the surface of T-cells infected with the leukemia virus, an effect not unlike the one Max Essex was seeing at Harvard. But they thought the reaction involved a protein that was part of the cell itself, not one that belonged to the virus. "We didn't believe it," Barre said in a recent interview in Paris, pointing to a page in her lab notebook where the data is marked with an arrow. "We didn't think it was reacting with the virus."

There were other surprises. Montagnier said he thought Gallo had added the sentence saying the French virus was a member of the "HTLV family" to the abstract rather than to the text of the paper. It was also his understanding, he said, that Gallo had agreed to change what the "L" in HTLV stood for from "leukemia" to "lymphotropic," meaning a virus that has an attraction for white blood cells.

Whatever the French had found growing in BRU, they knew it wasn't a leukemia virus, and Montagnier wasn't even sure the viruses were closely enough related to bear the same general name. "I believed myself that this was wrong," Montagnier recalls, "but I could not really say this is wrong to Gallo, because I had too little evidence at that time."

Although the antibody reactions and the distinctions between the core proteins were crucial to understanding what the French had discovered, they were lost on those who wrote the government news releases and those who read them. A typical report was the one in the Washington Post, which announced that three independent groups of researchers, at Harvard, the National Cancer Institute and the Pasteur Institute, had "all found signs of human T-cell leukemia viruses" in patients with AIDS and pre-AIDS.

Even those scientists working in the same field were confused by the abstract of the French paper. "Everyone thought the French had isolated HTLV too," recalled Jay Levy, a virologist at the University of California medical center in San Francisco. As it began to dawn on the French that their work was being viewed not as an original and potentially important discovery but merely as support for the findings of Gallo and Essex, the elation in Paris gave way to dismay. "We were not very happy," Francoise Barre recalls with her typical understatement. "That's for sure."

Gallo's response to the expressions of displeasure from Paris was to portray the Pasteur group as ingrates whose paper would never have been published in Science without his intercession. "When Montagnier's paper was submitted to Science, I held back mine so he could join," Gallo said in a telephone conversation with The Tribune last year. "No one's ever written this—I don't think I've ever told a reporter before—that Montagnier's paper was rejected by Science, that I intervened and got it accepted. Doesn't that tell you a little bit about my motives?"

Montagnier is unaware of any such rejection—"all I ever heard," he says, "was that my paper had been accepted"—and correspondence from Gallo's files shows that he forwarded the paper to Science with his glowing review just four days after it reached Bethesda. Asked how the French manuscript could have been rejected by other reviewers during the short time it was in Gallo's hands, Ruth Kulstad, the Science editor who handled the paper, would say only, "Everything here is confidential, and we do not discuss papers, authors or referees."

Nearly five years later, sitting in his cramped office in the virology complex at the Pasteur Institute, Luc Montagnier remembered Gallo's motives less than charitably.

"He was not against me writing a paper," Montagnier said, "but he thought my paper would support his own paper on HTLV. Because he thought my virus was HTLV. Gallo didn't believe there could be more than one kind of human retrovirus. He was fully convinced that HTLV was the right one, that there was only one human retrovirus involved in AIDS."

2 The father of human retrovirology

Retroviruses have fascinated scientists since they were discovered in animals early in this century. Until Gallo's HTLV, however, the only known retroviruses were those that caused cancer and other diseases in animals, and a small group of foamy-looking retroviruses in humans that didn't seem to cause any disease at all.

The idea that retroviruses might have something to do with cancer in humans had been talked about for years, and it was a prospect that had vast implications for medicine. If it were possible to "catch" some kinds of cancer the same way one caught polio or smallpox, it might be possible to wipe out such cancers through vaccination the same way polio and smallpox were being eradicated.

When then-President Richard Nixon signed the National Cancer Act of 1971 and declared his "war on cancer," there was genuine hope that the effort might ultimately produce a cancer vaccine. But the promise of those early years has gone almost entirely unfulfilled. Only one human retrovirus, Gallo's HTLV, has been indisputably linked to cancer, a rare cancer called adult T-cell leukemia.

There was more reason for hope in the spring of 1970, when researchers at the University of Wisconsin and the Massachusetts Institute of Technology announced their nearly simultaneous discoveries of an enzyme called reverse transcriptase, the missing piece to the puzzle of how human retroviruses work.

When David Baltimore, the MIT scientist who would share the Nobel prize for reverse transcriptase with Wisconsin's Howard Temin, was invited to the National Institutes of Health to talk about his great discovery, Gallo was in the audience. "After Baltimore had finished speaking," one of Gallo's associates recalled, "Bob came right back up and said, this is what we're going to work on."

Baltimore and Temin had found reverse transcriptase in cancer cells taken from mice and chickens, but if the human cancer virus program was going to go forward somebody would have to find it in human cancer cells. Within a few months Gallo had obliged, publishing a paper reporting the discovery of reverse transcriptase in human leukemia cells.

It looked at first like another historic breakthrough, important enough to put Gallo on the same program with Baltimore and Temin at the Nobel ceremony in Stockholm. But no one who attempted the same experiments could reproduce Gallo's results, and reproducibility is the acid test of science.

Throughout the early 1970s Gallo continued to refine his test for reverse transcriptase, but his periodic reports of new detections of the enzyme in human cancer cells were met with varying degrees of skepticism by his fellow scientists. If Gallo could keep finding reverse transcriptase in human cancer cells, they wondered, why couldn't he find the retrovirus that was producing it?

It was a reasonable question and, in January of 1975, Gallo and a National Cancer Institute colleague named Robert Gallagher announced that they had found the first human cancer retrovirus, called HL-23, in some leukemic blood cells from a woman in Texas. Despite the scientific convention that frowns on announcing important breakthroughs in the news media, reports of Gallo's discovery were in the newspapers before his landmark article was in print. "I got up one morning and read the headlines of the Washington Post," Gallagher recalled. "I was shocked to find that he'd been talking to the press."

It was a great moment while it lasted—"a great Eureka," Gallo called it at the time—but it lasted for only a year. A group of American and British virologists, attempting to confirm his historic find, discovered that the first human cancer virus wasn't human at all but a cocktail of monkey, ape and baboon viruses.

Gallo tried to explain his error by suggesting that the Texas woman had somehow been infected with the baboon virus, but there was really only one conclusion to be reached: Gallo's culture had been contaminated in his laboratory. Gallo first attributed the contamination to "sabotage by my enemies"; now he says, "Who the hell knows?"

Whatever happened to HL-23, by the time it was discredited most of the bright young researchers who had enlisted in the hunt for a human cancer retrovirus had concluded there probably was no such thing, at least not in solid, or tumor, cancers of the breast, colon and lung, and they were the most common.

As Gallo's erstwhile colleagues departed the NIH campus for academia and private industry, they joked that human tumor viruses might as well have been called "human rumor viruses." Now that viruses were passe, the smart money in cancer research was betting on so-called "cancer genes," pieces of defective DNA that somehow trigger the cancerous proliferation of ordinary cells. The cancer crowd also joked about HL-23. Gallo remembers more than one occasion when, preparing to speak at a scientific meeting, he was greeted with derisive laughter.

The question of whether viruses might be involved in blood cancers like leukemias was technically still open. In 1978, scientists in the Netherlands not only detected reverse transcriptase but also photographed what looked like a retrovirus in cells from several patients with an uncommon kind of T-cell cancer known as mycosis fungoides.

But the Dutch weren't able to say much about the new retrovirus, or even whether it was actually responsible for their patients' disease. In order to prove that the virus was causing mycosis fungoides they would need to find it in a much larger number of patients, and they couldn't. "We tried," recalled Elizabeth van der Loo, who as a young graduate student was chiefly responsible

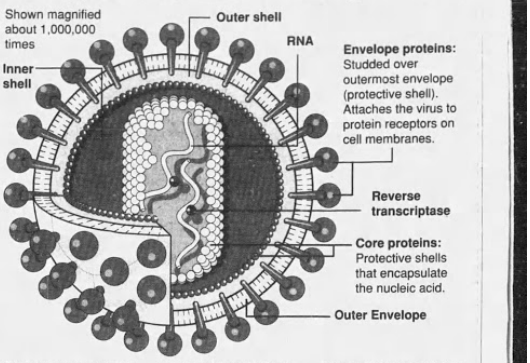
Anatomy of a Human Immunodeficiency Virus (HIV)



RNA (ribonucleic acid): Important in protein synthesis and genetic transmission and is found in all cells and many viruses. Nucleic acids are the chemicals that control cellular heredity and function. All viruses consist of nucleic acid, either RNA or DNA (deoxyribonucleic acid), but never both.

Reverse transcriptase: An enzyme that acts as a biological trigger, stimulating the formation of DNA on a template of RNA in certain viruses composed of RNA, a process crucial to the retrovirus life cycle. The flow of information from RNA to DNA is the reverse of the normal information pathway, hence the name.

Proteins: The tool kit and framework of all cells and components of viruses. They can also serve as enzymatic catalysts that cause or accelerate chemical reactions. Proteins are polymers, long strings of amino acids attached to one another like beads in a necklace to form a larger, more complex molecule.

How subtle invader destroys cells that control the body's defenses

The virus that causes AIDS is one of hundreds that inhabit humans, animals, insects, plants—even bacteria. Viruses can take many sizes and shapes. Some are harmless; others cause disease ranging from smallpox, polio and measles to yellow fever, herpes and flu.

Viruses are very small—a hundred times smaller than even bacteria. And, while some are more complex than others, they are among the simplest things on earth: a tiny shred of genetic information tucked inside a protein shell and sometimes covered with an envelope of fatty material. Viruses are not alive. They can reproduce themselves, but only after they have invaded the cells of their preferred host and gained control of the cells' genetic machinery.

Once inside the cell the virus begins its reproductive process, spewing forth new virus particles at such a rate that the cell is destroyed. A single virus can reproduce itself thousands of times in a matter of hours, which is why people who contract most viral diseases become ill a short time after infection.

All the diseases that have been linked to viruses result in some way from the process of infection. The leukemia virus called HTLV-1 infects mainly helper T-cells, the controllers of the human immune system, and causes them to multiply out of control. The AIDS virus infects the same kind of cells but kills them, leaving the body vulnerable to a variety of potentially lethal infections.

The genetic material of many viruses is DNA, a chain of molecules called nucleotides strung together in a sequence that spells out the life-code for every living thing from people to potatoes. When a DNA virus infects a cell, it begins the reproductive process by employing its cousin, RNA, to assemble amino acids into the catalytic proteins, called enzymes, that it needs to construct more copies of itself, and then to assemble the structural proteins that form new virus particles.

The genetic codes of some viruses, like the AIDS virus, are written not in DNA but in RNA. Such viruses, called retroviruses, use an enzyme called reverse transcriptase to copy their original genetic RNA into a complementary strand of DNA that inserts itself into the much larger strand of human DNA in the host cell.

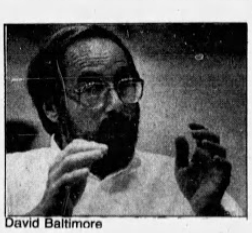
A historical look at AIDS research from 1970 to 1987

JUNE 27, 1970: **Howard Temin** and **David Baltimore** discover reverse transcriptase in cancer cells from mice and chickens.

DEC. 5, 1970: **Robert Gallo** first reports finding reverse transcriptase in human leukemia cells. The report is viewed with skepticism by fellow scientists.

JAN. 31, 1975: **Gallo** announces the isolation of the first human cancer virus, HL-23. It later proves to be a cocktail of monkey and baboon viruses.

SEPTEMBER, 1977: Japanese scientists report an epidemic of disease they call adult T-cell leukemia (ATL) in that country's southwestern provinces.



David Baltimore

1979: Dutch researchers report finding and photographing retrovirus particles in patients with a kind of cancer called mycosis fungoides.

MARCH, 1980: NCI's **Adi Gazdar** reports the establishment of the permanent T-cell lines HUT78 and HUT102, the latter from a 27-year-old mycosis fungoides patient named **Charles Robinson**.

DECEMBER, 1980: **Bernard Poiesz** and **Frank Ruscetti** report the isolation of the first human cancer virus, HTLV, from **Charles Robinson's** cells.

MARCH 24, 1981: At a meeting in Kyoto, Japan, **Gallo** learns **Yorio Hinuma** has found antibodies to a viral antigen in 100 percent of Japanese patients with ATL. **Gallo** tells the group he has found antibodies to HTLV in "some" ATL patients.

JUNE, 1981: UCLA's **Michael Gottlieb** reports first six cases of what will later be called AIDS.

FEB. 19, 1982: **Gallo** publishes data showing antibodies to HTLV in blood from Japanese ATL patients, suggesting his virus may be the same as that detected by the Japanese.

How the AIDS retrovirus attacks the helper T-cell

1. AIDS virus enters the human circulatory system.

2. Virus specifically targets a cell in the human immune system, known as the helper T-cell. It attaches itself to a special receptor that is on the outer wall of the T-cell.

3. Virus is absorbed into the host cell, shedding its outer shell and releasing its own genetic code (RNA) along with the reverse transcriptase enzyme.

4. Enzyme uses the viral RNA to manufacture a DNA copy of itself.

5. Viral DNA inserts itself into the host cell DNA, where it may lie dormant for up to 10 years.

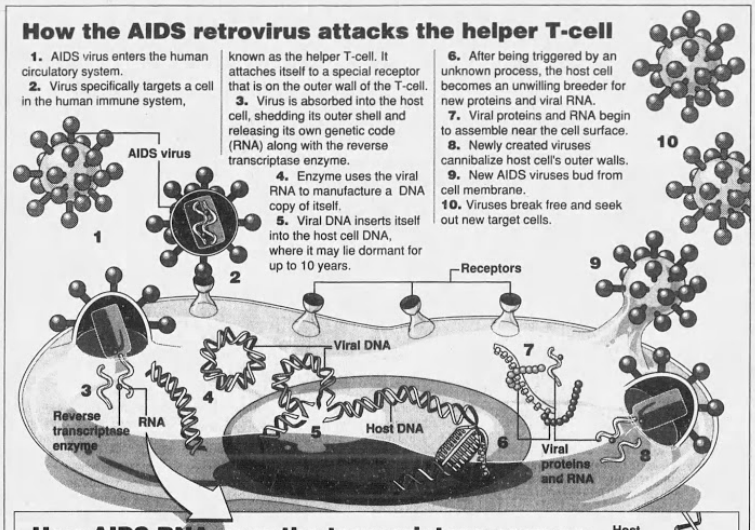
6. After being triggered by an unknown process, the host cell becomes an unwilling breeder for new proteins and viral RNA.

7. Viral proteins and RNA begin to assemble near the cell surface.

8. Newly created viruses cannibalize host cell's outer walls.

9. New AIDS viruses bud from cell membrane.

10. Viruses break free and seek out new target cells.



How AIDS RNA uses the transcriptase enzyme

Normal DNA contains the nucleotides adenine, cytosine, guanine and thymine (A,C,G and T). Instead of thymine, RNA uses uracil or U.

1. The reverse transcriptase enzyme uses the AIDS virus single-strand RNA as a template to create a complementary strand of DNA from nucleotides found in the host cell. RNA also has a slightly different composition of the sugar phosphate backbone that holds the nucleotides together.

2. This creates an RNA-DNA double-helix.

3. A DNA copy of the RNA half is made, which then replaces it.

4. The new DNA double helix strand contains the AIDS virus coding.

5. The viral DNA inserts itself into the host cell's DNA, directing the host cell to produce more RNA and proteins to create new AIDS viruses.

for the discovery. "But in Holland there are not so many patients with mycosis fungoides."

Gallo's lab, which in the wake of the monkey virus contamination had all but stopped looking for a human cancer virus, had been reduced to publishing papers on the biochemistry of the blood. The initiative to renew the search came from a young physician named Bernard Poiesz who joined the lab in the fall of 1978 as a postdoctoral fellow.

Poiesz had elected to work under one of Gallo's associates, a young cell biologist named Frank Ruscetti, who had just made a great leap forward in the laboratory technique for growing T-cells. With another Gallo assistant named Doris Morgan, Ruscetti had discovered and isolated the protein, now called Interleukin-2, that the human immune system uses as a biochemical signal to encourage T-cells to divide and multiply in response to an infection.

The first year of Poiesz's fellowship had been spent with cancer patients, and he had seen a number with the T-cell cancers that are known as lymphomas. What he wanted, he told Ruscetti, was to continue looking at cells from such patients in hopes of finding a clue to what caused their disease.

The research from Holland had not yet been published, and Poiesz had no real reason to expect to find that lymphomas were being caused by a human cancer virus. But he had learned the art of testing cells for reverse transcriptase as a medical student at the University of Pennsylvania, and "it seemed reasonable to look, because we knew how to look."

Among the first cells Poiesz got to look at were some taken from the lymph node of one of his former patients, a 28-year-old Alabama man named Charles Robinson. "I actually wound up being the fellow that admitted him for the lymph node biopsy," Poiesz says, "not realizing what that lymph node biopsy was going to get us all into."

Robinson had been diagnosed as having mycosis fungoides, the same kind of T-cell cancer as Elizabeth van der Loo's patients. Before Robinson died, however, another cancer institute researcher named Adi Gazdar mixed some of Robinson's cancerous T-cells with Frank Ruscetti's Interleukin-2. The result was a continuous T-cell culture called HUT102, in which Robinson's leukemic T-cells would go on dividing and multiplying in the laboratory long after he was dead.

When Poiesz and Ruscetti began looking at the cells from HUT102 shortly before Christmas of 1978, they found measurable levels of reverse transcriptase. But Poiesz was aware that scientists in Gallo's lab and elsewhere claimed to have detected reverse transcriptase in human cancer cells before. There had been so many false alarms, Poiesz recalled, that "in order for something to be considered interesting there had to be an extraordinary amount of reverse transcriptase."

Because Robinson's cells were showing only a small amount of enzyme activity, Poiesz said, "many people were very skeptical. But I had done enough reverse transcriptase assays on normal T-cells to recognize that if there was a little bit of production, that's all you needed to see to be interested."

In fact, Poiesz and Ruscetti were more than interested. Over the next few months they worked night and day, growing huge quantities of Robinson's cells and trying to isolate, purify and analyze the virus they appeared to contained. "I grew 120 liters of it and saw that it didn't behave like anything else," Poiesz said, "yet it clearly was a retrovirus. We knew that we had stumbled onto something that was different."

Their main concern was that whatever virus was reproducing in Robinson's cells might be one of the many animal retroviruses that were being grown elsewhere in the same building—and which, in a bizarre reprise of the HL-23 fiasco, might have somehow contaminated their cultures. Painstakingly, the two researchers checked their cultures for every one of the dozens of known animal retroviruses. When there were no more animal viruses left, Poiesz recalled, "We knew we had something."

But they were unable to give the good news to Gallo, who was on an extended trip out of the country. "I'd proceeded to do the additional work while he was away," Poiesz said. "He was gone for a couple of months." When Gallo found out that what appeared to be the first human cancer retrovirus had been isolated in his lab, it was in a conversation with another scientist at a backyard cocktail party in Bethesda. "He had just come home that weekend," Poiesz recalled. "I was supposed to have a meeting with him on Monday. I must say he was a little ticked at us."

Considering that he had spent much of the previous decade looking for the first human cancer virus and then enduring the derision of other scientists after he mistakenly claimed to have found it, Gallo's annoyance was understandable to Poiesz. "He was a bit astounded that this had happened," Poiesz said, "because they had tried so long to find a retrovirus. Some very skilled people had tried it, and here was a junior member of the team, a postdoc, and in the first month of working he finds the human retrovirus. That seemed too lucky to be true."

To top it off, Poiesz and Ruscetti had been lucky not just once but three times out of three, finding what looked like the same new virus in a Caribbean islander and in a man from Boston. By then, another researcher in Gallo's lab recalled, there was "quite an uproar about the rest of the people in Gallo's lab not having been included in the discovery. Basically, they had opted out because they didn't believe Bernie in the first place. Then at that point Gallo kind of took over."

In December of 1980, a paper reporting the isolation of a new human retrovirus from a patient identified only as "CR" appeared in the distinguished monthly Proceedings of the National Academy of Sciences. The paper's first author was Bernie Poiesz, with Frank Ruscetti second. Gallo's name was last.

Gallo has called the discovery of HTLV "one of the most exciting stories of 20th Century biology," and it soon earned him informal recognition as "the father of human retrovirology." In keeping with scientific tradition, Gallo also gave the new virus its first name: human T-cell lymphoma virus.

What Gallo's associates remember most, however, was his disappointment that the new virus had not been found in a patient with leukemia, but in one with a lymphoma, mycosis fungoides, which affects far fewer people. "We argued whether it should be lymphoma or leukemia," Poiesz said. "I wanted to not even say it was a human virus until we knew for sure, but HTLV is the name that he wanted it to be."

As would have been true of any report of any new human virus, particularly one announcing the first human cancer retrovirus and especially one from the lab where the HL-23 debacle had occurred just five years before, the HTLV paper attracted a great deal of attention. But once the initial excitement had begun to fade, it became clear that the most important questions remained unanswered.

Although its name implied that the new virus was the cause of T-cell lymphoma, or at least played some central role in the disease, there is no way to be sure a virus isolated from a single patient, or even three such patients, is anything more than a laboratory curiosity. "It was clearly very different and we clearly had it in three humans at that point in time," Poiesz says. "But we hadn't proven that it had caused disease, nor did we at that point have any idea about what was really going on."

When Poiesz and Ruscetti began testing other mycosis fungoides patients for the virus, they couldn't find a single person who was infected, which meant that whatever the virus did, it probably didn't cause mycosis fungoides. "We were striking out," Poiesz says. "At that point it hadn't dawned on us that there might be an epidemic somewhere else in the world."

There was such an epidemic, but it was a long way from Bethesda and it involved a different disease. In the fall of 1977, a year before Bernie Poiesz arrived in Gallo's lab, a team of Japanese medical scientists in Kumamoto had published the first report, in the American journal Blood, of a newly recognized disease they called adult T-cell leukemia, or ATL for short.

A handful of other diseases had previously been discovered that involved the cancerous proliferation of T-cells, but these Japanese cases were unlike anything seen before. Not surprisingly, the urgency to find out what ATL was all about was greatest in the country where its victims lived. Within a few months, a researcher at the Okayama Cancer Institute named Isao Miyoshi had succeeded in growing T-cells taken from a 69-year-old man who had died four months after coming down with ATL.

From the way the old man's cells behaved in the lab, Miyoshi concluded that there must be something in his culture that was being transmitted from one cell to another. The most logical thing was a virus; and because the cells were producing reverse transcriptase, it seemed likely to be a retrovirus. When Miyoshi sent some of the cells to Yorio Hinuma, the eminent Kyoto virologist, Hinuma could see retrovirus particles under an electron microscope.

Three months after Poiesz and Ruscetti's paper electrified the scientific community, Gallo traveled to Kyoto to attend a hastily called meeting to discuss recent developments in human retrovirology. A short time before, Gallo's lab had received some blood samples from Japanese ATL patients sent by another Kyoto researcher, Yohei Ito, who had heard about Poiesz's paper and who wondered whether this new virus called HTLV might have something to do with ATL.

When Gallo's turn came to speak, he reported that some of the blood samples he got from Ito had contained antibodies that reacted with his virus—an indication that some of the Japanese ATL patients might be infected with a virus like HTLV-1. But Hinuma had done some similar experiments, and his results were more conclusive.

Hinuma had mixed Miyoshi's cells with serum, the liquid component of blood that remains after the cells have been removed, that had been taken from a number of patients with ATL. In each case, when the cells were placed under an ultraviolet light, a high percentage of them lit up—evidence that the serum from every single patient, not just some, contained antibodies that were reacting with something foreign in Miyoshi's leukemia cells.

Although he was too cautious to call it a virus at the time, the "something foreign" proved to be the retrovirus Hinuma had photographed. The Japanese named it ATLV, for adult T-cell leukemia virus.

"The Japanese work was driven by studying the pattern of the disease. Gallo's work was driven by coming across this virus and being unaware of ATL," says Robin Weiss of the Institute of Cancer Research in London, a noted retrovirologist and a coauthor of the definitive textbook on human retrovirology.

"Hinuma did that beautiful work," Weiss said. "I think he deserves real credit for that. I think Ito probably deserves the credit for saying this new virus of Gallo's might have something to do with this disease. I'd give Miyoshi the fine credit. Miyoshi's a modest and quiet man; he's continued to do super work in the field."

Except for the Japanese, Gallo's HTLV might well have remained a virus in search of a disease. But now that the Japanese patients were known to have antibodies to both Gallo's virus and to ATLV, it was important to know whether the two viruses were the same. The best way to find out was to crack their genetic codes—literally, to take them apart, identify their genetic building blocks one by one, and then compare them side by side. Although Gallo's assistants struggled with the problem for months, they were unable to clone their virus, a crucial step in breaking its code.

"To be honest," Bernie Poiesz recalls, "the people that were capable of cloning back at NIH were not all that interested. They didn't fully believe the story and they had other priorities. The Japanese worked very fast and very hard. They beat us to the punch."

In the summer of 1983, when scientists in Tokyo published the genetic sequence of ATLV, they managed even without a comparable sequence of HTLV to determine that the two viruses were "very similar." Later experiments appeared to show that the two viruses were in fact the same, which led to a final question: How could the same virus that caused adult T-cell leukemia in Japan have been discovered in Charles Robinson, a patient with mycosis fungoides who had never been anywhere near Japan?

The question became more compelling after Yorio Hinuma, in collaboration with Abraham Karpas, a retrovirologist at Cambridge University in England, reported that every mycosis fungoides patient they tested was negative for antibodies to ATLV. Not long afterward, Gallo and the cancer institute's clinicians concluded that Robinson had not died from mycosis fungoides but from a new kind of T-cell cancer that was much more like adult T-cell leukemia.

In scholarly articles recounting the discovery of HTLV, Gallo began referring to Charles Robinson as a patient with "leukemia-lymphoma," and then simply as someone who had died of adult T-cell leukemia. Although its initials stayed the same, the name of Gallo's virus changed as well: from human T-cell lymphoma virus, to human T-cell leukemia-lymphoma virus, and finally to human T-cell leukemia virus.

With the discovery of HTLV, the humiliation of HL-23 was nearly forgotten—and so, at least by Gallo, were the early contributions of the Dutch and the Japanese. Before their first paper on HTLV was published, Poiesz said, he and Ruscetti had given copies of both the Van der Loo paper from Holland and the one reporting the ATL epidemic in Japan to Gallo, with the suggestion that he might want to mention them in a footnote. He didn't.

In one scholarly article he authored later on the discovery of HTLV, Gallo awarded the Japanese two footnotes out of 85. In another, he gave his own lab credit for having established the link between the virus and adult T-cell leukemia, which was really something Hinuma and Miyoshi had done. To a colleague who asked for recommended reading on HTLV, Gallo sent a list of his own publications. "Much of the additional work," he wrote, "most of it from Japan, is really not terribly relevant. There are a few publications from Holland but they do not say anything particularly new."

When Gallo won his first Lasker prize in November of 1982, for the discovery of HTLV, there wasn't any mention of Bernie Poiesz or Frank Ruscetti. "When people talk about HTLV, it's always Gallo, Gallo, Gallo," an NIH scientist says. "You don't hear Bernie Poiesz's name, and you never hear Frank's name."

After Poiesz's postdoctoral fellowship was over he moved to Syracuse, where he now heads the division of hematology-oncology at the State University of New York Medical Center. When he used Gallo as a reference in applying for a grant to continue his work with HTLV, Poiesz recalls that Gallo responded with an unflattering letter.

"He basically wanted to make sure that he was the major player as the theme of HTLV worked its way out into the world," says Poiesz, who did go on working with HTLV. "I think his competitive nature was such that for some reason there was a false sense of concern that I might do well with it."

From his vantage point in Upstate New York he has watched while his former boss has taken the center stage of science. "There's many different reasons why people associate Bob Gallo's name as the discoverer of HTLV," he says. "I can't change how people perceive it, or how people presented it to the media. The only thing I can do is do my work. I spent many, many nights in that laboratory. The moment of discovery was mine."

In the years immediately following that discovery, Frank Ruscetti fared less well. "Frank's a relatively strong person and Bob's a pretty strong person," says one man who knows both of them. "There was a particular enmity between them for some time. There was a pyramid and Bob Gallo was the boss."

Before long Ruscetti was not only out of Gallo's lab but out of science altogether. It was nearly two years before he would find his way back in, at a National Cancer Institute satellite facility in Frederick, Md., where he is still

employed. "My battles with Gallo were legendary," Ruscetti says, "but I won't talk to you. I just keep my mouth shut and try to do science."

When Gallo wrote the official history of his research on AIDS and human retroviruses, he recorded that the first human cancer virus, HTLV, had been discovered by "Gallo, Poiesz and coworkers." Asked about the history of that discovery last year, Gallo replied, "I think I've forgotten more than Poiesz and Ruscetti ever knew, times 10."

3 'You have to let Jean-Claude speak'

In the spring of 1983, while Bernie Poiesz was still enjoying the memory of a postdoctoral fellowship that had produced an almost unheard-of 11 major papers, and while Frank Ruscetti was still looking for work, Robert Gallo was channeling the search for the source of AIDS in the direction of the leukemia virus they had discovered.

But even as Gallo was promoting the virus, which he now called HTLV-1, in interviews and letters to his colleagues as the "leading candidate" for the cause of the AIDS epidemic, experiments in his own laboratory were producing persuasive evidence that HTLV-1 had nothing to do with AIDS.

At Harvard, Max Essex was finding ever-higher percentages of AIDS patients positive for what he said were antibodies to the leukemia virus. But Gallo's assistants had also begun testing AIDS patients' blood samples with a more specific test, one that measured antibodies to the virus itself, not to a mysterious protein on the surface of virus-infected cells, and they were obtaining very different results.

A few weeks before Gallo's papers on the possible link between the leukemia virus and AIDS were published in Science in May, 1983, one of Gallo's assistants sent him a note reporting that only 17 AIDS patients "out of a much larger number tested" had so far proven antibody-positive. The following month, Gallo acknowledged in a memo to a senior cancer institute official that, despite Essex's impressive numbers, his own lab was finding that most AIDS patients were not infected with HTLV-1.

Gallo's staff had also detected the leukemia virus itself, not just antibodies to the virus, in a small number of AIDS patients like Claude Chardon. But except for the four detections that Gallo reported in Science and a handful of others, efforts to find the virus in other AIDS patients had been unavailing. Lee Ratner, a molecular biologist who joined Gallo's lab as the hunt for HTLV-1 in AIDS patients was gathering speed, recalled that Gallo's assistants had looked for the virus in "something like a hundred" AIDS patients and that all of them were negative.

Gallo didn't report the low numbers of AIDS patients who had antibodies to the leukemia virus or who were infected with the virus itself. As the negative data piled up behind the scenes, Gallo continued to make the case for his virus in public. "The evidence is certainly accumulating," he told the Journal of the American Medical Association in June of 1983, that HTLV was "the best lead yet found" for the cause of AIDS.

In addition to overseeing the other operations of his cancer laboratory, in the spring of 1983 Gallo was spending increasing amounts of his time on AIDS—so much that, in April, he complained in a letter to a Japanese scientist that "the pressure on me is unusually severe." The reason, he said, was that he had just accepted an "additional new responsibility" as scientific director of a new cancer institute task force on AIDS.

When the task force held its first formal meeting in July, Luc Montagnier, chief of cancer virology at the Pasteur Institute in Paris, flew in to attend. In response to an appeal from Gallo, Montagnier brought a tiny vial containing a sample of the virus the French believed to be the cause of AIDS. In April, the French had sent Gallo a tiny vial of viral DNA. Gallo said it hadn't been enough. "We desperately need more DNA," Gallo wrote Montagnier a few days later. "The data is critical for you, us and the field so please do everything possible to get a good amount of DNA to us as soon as possible."

To the three dozen members of the task force Gallo said what he had been saying in public, that his leukemia virus made a "very attractive" candidate for the cause of AIDS. But Montagnier had brought data on new isolates of the French virus taken from other patients with AIDS, and also some photographs of the virus he hadn't published in Science. "I was reluctant to show them in the paper," Montagnier explained later, "because people would say it was just a viral contamination with something else."

The new pictures were viewed with a careful eye by Matthew A. Gonda, the chief of the cancer institute's electron microscope facility in Frederick, Md. Gonda had recently written a paper on a class of animal retroviruses known as lentiviruses, slow-acting retroviruses that until then had been found only in goats, horses and sheep and whose barlike core is readily distinguishable from the disc-like core of HTLV-1.

It looked to Gonda like the virus the French were now calling LAV had to be a lentivirus too. When Gonda wrote a memo to that effect, recalled Berge Hampar, the former general manager of the Frederick facility, "Gallo was really furious. The last thing he wanted to hear was that the French had a lentivirus, because if it was lenti that meant it wasn't HTLV. He called Gonda at home, ranting and raving. He screamed at him for an hour."

Scientific meetings at Long Island's venerable Cold Spring Harbor Laboratory have a special cachet. Apart from the laboratory's picturesque waterside setting, it has a history of producing good science. Its reputation derives largely from the fact that its director is James D. Watson, the American biologist who, with Francis Crick, solved the mystery of the double helix—the structure of DNA.

When Gallo and Essex were asked to organize an important conference on HTLV at Cold Spring Harbor for mid-September of 1983, they included a special forum on the known links between the leukemia virus and AIDS. Montagnier was among those invited to Cold Spring Harbor, and he had a good deal to say.

All summer the Paris group had been working with success to firm up the connection between its new virus and AIDS, and it had made some significant advances. When Montagnier learned he had been given just 15 minutes to speak, he protested. "I am asking you," he wrote to Gallo, "to allot me 30 minutes, and possibly not at the very end of the meeting."

The Cold Spring Harbor conference opened on the morning of Wednesday, Sept. 14, with a welcoming speech by Essex and an introduction by Gallo. For the rest of that day and most of the next, a succession of scientists reviewed various aspects of their work on Gallo's leukemia virus and its odd new cousin, HTLV-2.

When the session on AIDS began late Thursday afternoon, Essex began with the report that he had now detected leukemia virus antibodies in up to 70 percent of AIDS patients. He was followed by Gallo, whose talk highlighted "the possibility that HTLV plays an important role in the origin of AIDS." The next-to-last speaker was Montagnier, who had been given 20 minutes to speak instead of the half-hour he asked for and who was still at the end of the program. By the time he took the podium, many of those at the meeting had already left.

Since the beginning of the year, Montagnier began, the new French virus had been identified in a total of seven patients besides BRU, the fashion designer from whom it was first isolated. The French, moreover, had now found their virus in at least one member of every group in which AIDS seemed to be prevalent: three homosexuals, a hemophiliac and a Haitian.

They had also developed a test for antibodies to the virus. Since July, Francoise Brun-Vezinet, the physician who had delivered a piece of BRU's lymph node to the institute in January, had been growing the French virus in a special room in the basement of the Pasteur. The purified virus had been used to test for antibodies in dozens of AIDS patients' blood samples, including some that had been sent to Paris by doctors in New York.

The Pasteur tests, Montagnier said, were showing that more than 60 percent of patients with pre-AIDS, and nearly 20 percent of those with AIDS, had antibodies to the French virus. The same patients, however, had tested negative for HTLV. The two viruses, he said, seemed to be "clearly distinct." They didn't react biochemically, and when the French virus was looked at under an electron microscope it had an entirely different shape. The only other virus that resembled it at all was a lentivirus that caused infectious anemia in horses.

By all accounts, it was a dramatic moment. Montagnier was telling Gallo, and in front of many of his closest colleagues, that for the better part of a year he had been leading science down the wrong road. According to several of those present, when the time came for Montagnier to entertain questions Gallo rose to the attack, suggesting that the measurements of reverse transcriptase activity by the French had been flawed and that they hadn't isolated a retrovirus at all. "He told him it was terrible science," said a scientist who was there, "that there was no way it could be true."

"I went up to poor Montagnier afterwards," another scientist recalled. "He was sitting in the corner. He looked like he'd been beaten over the head with a sledgehammer. I said, 'The data looks good, I'm sure you've probably got it, don't take to heart what these guys have said to you.' "

Gallo now regrets his treatment of Montagnier. "He was definitely, definitely hurt and it certainly hurt our relationship badly," he told The Tribune. "I wouldn't do that again."

Montagnier's talk had gone far beyond the BRU paper in Science four months before, but many of those at Cold Spring Harbor were still not convinced by his data. For a few, however, the talk provided their first real understanding of the depth and importance of the French research on AIDS. The Science paper, recalled the British retrovirologist Robin Weiss, "turned out to be a seminal paper, but it didn't convince the world that this was the virus. His Cold Spring Harbor paper made me take that first one much more seriously."

Bernie Poiesz was in the audience that day. Like Gallo and Essex, Poiesz had been looking for evidence that the leukemia virus had something to do with AIDS, and he remembers thinking after Montagnier's presentation that the French might be right after all. "The data seemed to make sense," Poiesz said. "He obviously didn't have it fully developed, but he had gone a substantial way and it was plausible to me that they had found something that was different."

Impressive as the French data were, researchers who hadn't attended the Cold Spring Harbor meeting remained mostly unaware of the latest findings from Paris. One was the University of California's Jay Levy. In early October, in Paris for his brother's wedding, Levy stopped by the Pasteur to say hello. It was not until then, he recalled, "that I realized they did not have HTLV" but something completely different.

As an AIDS-causing agent, Levy said, the French virus "was almost too good to be true." It grew in the same helper T-cells that AIDS patients lacked, Levy said, and it killed them. "I came back to the hotel room and I told my wife, 'Sharon, I've been looking for this virus and I think they've found it.' But if I hadn't gone to see them I never would have known."

Within a few weeks, Levy would isolate the AIDS virus in his San Francisco lab, but he would not publish his discovery for several months after that. Levy wanted to make sure the virus, which he would call ARV, for AIDS-related virus, could survive the acid treatment used in the preparation of the clotting factor that keeps hemophiliacs from bleeding to death. If it couldn't, it was obviously the wrong virus and Levy would have to look somewhere else.

A few days after the September meeting at Cold Spring Harbor, one of Gallo's assistants sent him the latest draft of the still-unpublished paper reporting that only 8 percent of the AIDS patients they had tested had antibodies to HTLV-1. "Not sure he will want to publish on AIDS at this time," the assistant wrote to one of her colleagues, "but we'll see."

While Gallo pondered whether or not to publish, the French were having trouble getting their latest research into print. Their Science paper had shown that the French virus infected T-cells, but not which kind of T-cells. Since then, Paris immunologist David Klatzmann had proven that the virus had a particular affinity for infecting—and killing—the helper T-cell, precisely the same cells AIDS patients didn't have enough of.

Klatzmann's discovery made the most convincing case yet that the French virus played a critical role in the disease. Had it been published, Robin Weiss said later, "it would have added some weight, because it would have said this odd virus we have selectively grows in and kills the kinds of cells that disappear from AIDS patients."

In trying to determine the attraction of the virus for helper T-cells, Klatzmann had used blood samples taken from a young hemophiliac who had been injected regularly for years with a clotting factor known as Factor VIII, some of which had been made from blood tainted with the AIDS virus. What was significant was that, unlike all the other patients in whom the French had found the virus, this young man was perfectly healthy.

In the summer of 1983, no one suspected that infection with the AIDS virus would be as widespread as it is. Fewer than 2,000 Americans were then ill with the disease, and many doctors assumed that, as with most contagious diseases, illness set in a short time after infection. By isolating their new virus from someone who was still healthy and had been infected for some time, the French had discovered the phenomenon of the "healthy carrier," those infected but symptom-free individuals who, by unwittingly infecting others, had spread the virus through large populations of gay men and heroin users.

When Klatzmann and the Pasteur group sent a paper describing the affinity of the AIDS virus for helper T-cells to Nature in the summer of 1983, the paper was summarily rejected. One of the journal's reviewers had only a few technical criticisms, but the other dismissed it out of hand. If what the French were saying was true, the second reviewer wrote, it would be a very important paper. He just didn't think it was true—it sounded to him like what the French had was a mouse virus contaminant.

The authors quickly resubmitted their paper to an American journal, the Proceedings of the National Academy of Sciences. One of that journal's reviewers thought the paper should be published forthwith, but the second reviewer never replied. When Klatzmann encountered the man at an AIDS conference in Atlanta two years later, he recalled, "he told me that he had been too busy."

While many of those attempting to treat AIDS patients were under the misapprehension that Gallo's leukemia virus, or one very much like it, was the cause of AIDS, the French continued to try to make their voices heard. Because of the difficulties they were having in publishing their papers, the French decided to use important scientific meetings like the one at Cold Spring Harbor to spread the word of their discoveries.

But when Klatzmann presented his unpublished data to a meeting of the New York Academy of Sciences in November, his talk didn't produce many headlines. "The journalist from the New York Native [a weekly newspaper with a mostly homosexual readership] called and he did interview me, actually," Klatzmann recalled. "I was also interviewed by Channel 13," the public broadcasting station in New York, "but I was told later that they took off my part."

Despite the ongoing work in Paris, Gallo's human leukemia virus was still the hottest thing in virology. But even as Gallo was adding the American Cancer Society's medal of honor to his prizes and awards, the case for HTLV-1 as the cause of AIDS was beginning to collapse under its own weight. According to the minutes of the November meeting of Gallo's AIDS task force, that month's discussion focused on what to do about "the continuing problem" posed by the still-unpublished data showing that very few AIDS patients were infected with the leukemia virus.

Part of the problem was that the negative data were no longer coming only from Gallo's lab. One task force member had found only a single AIDS patient out of 59 positive for antibodies to the Gallo virus, and a handful of scientists outside NIH were now questioning Gallo's thesis in public. Some weeks earlier, a Boston University researcher named Paul Black had sent a letter to the New England Journal of Medicine suggesting that Gallo's leukemia virus was "unlikely to be in itself the cause" of AIDS. In an interview with the Associated Press, Black dismissed Gallo's research on the connection between AIDS and the leukemia virus as "hype."

Gallo was not pleased. "There are people who were writing letters at that time in the New England Journal saying we were nuts," Gallo recalls. "Paul Black. I know Paul, I regard him as a colleague and friend and I didn't understand why he wrote it. I called him up on the telephone and argued with him."

Although Black's objections were founded on intuition, a few other labs had been compiling the same sort of negative antibody data that Gallo had in his lab. But it was proving as difficult for the others as for the French to find their way into print.

Sometime in 1981 a Manhattan physician named Joseph Sonnabend first began seeing a few mysterious cases of what would later be called AIDS. Like other doctors in New York and San Francisco, Sonnabend was interested in learning as much as possible about the disease that was killing his patients. When Gallo began suggesting two years later that HTLV-1 played an important role in AIDS, Sonnabend started taking blood from his patients to be tested for antibodies to Gallo's virus.

The tests were conducted by Shinji Harada, who was spending a year at the University of Nebraska and who already knew a lot about the leukemia virus. Before coming to Omaha, Harada had investigated on his own the idea that the virus might have something to do with AIDS, but he hadn't found any connection.

When Sonnabend's blood samples arrived in Omaha, Harada ran the same tests again, and with the same results. "AIDS patients had no antibody against HTLV," Harada says.

Just to be sure, Harada forwarded some of the same samples to scientists in two other laboratories. One was Yorio Hinuma, the Kyoto University virologist who established the first link between Gallo's new human retrovirus and adult T-cell leukemia. The other was Abraham Karpas, a retrovirologist in the department of hematological medicine at Cambridge University in England. Both Hinuma and Karpas confirmed Harada's results in short order.

When the Sonnabend group wrote up its findings and sent the paper off to several major journals, none of them was interested. Sonnabend had recently taken on the task of editing a new journal devoted exclusively to AIDS, and in his capacity as editor Sonnabend decided to publish his own paper. "I toned it down somewhat," he recalls; "which I sort of regret now. I even added a sentence at the end, to the effect that maybe the difference between our results and Gallo's could be attributed to the different geographical ori-

APRIL 12, 1983: At **Gallo's** urging, Pasteur researchers begin writing a paper reporting the discovery in **BRU** of what they believe is a new human retrovirus different from HTLV.

APRIL 15, 1983: A Pasteur technician delivers the French paper to **Gallo** in Bethesda.

APRIL 19, 1983: **Gallo** sends a second paper to Science reporting the isolation of HTLV from one of the East Coast homosexuals and detections of the virus in **Marcellin** and **Chardon**. Same day, he sends the French paper to Science with a letter urging that it be published.

APRIL 27, 1983: Harvard University applies for a patent on the Essex test for antibodies to HTLV.

MAY 5, 1983: An assistant informs **Gallo** that, using a test different from the one developed by **Essex**, only 17 AIDS patients have tested positive for antibodies to HTLV "out of much larger number tested."

MAY 20, 1983: The three papers by **Essex** and **Gallo** reporting evidence of HTLV in AIDS patients are published in Science. A fourth paper, the one reporting the isolation of a retrovirus from **BRU**, is largely overlooked.

JUNE, 1983: **Gallo** informs his superiors that, despite **Essex's** published data, experiments in his lab show most AIDS patients are not infected with HTLV.

JUNE, 1983: Japanese researchers publish the first genetic sequence of ATLV; they suggest ATLV and HTLV-1 are "very similar."

JUNE, 1983: Pasteur researchers begin growing the **BRU** virus, now called LAV.

JUNE 3, 1983: **Gallo** tells scientists at the Centers for Disease Control HTLV is still "the best published lead to date" for the cause of AIDS.

JUNE 22, 1983: Pasteur researchers say they have found antibodies to LAV in six homosexuals with pre-AIDS and have detected the virus itself in four of the six. **Gallo** tells a reporter HTLV "is providing the best lead yet found" for the cause of AIDS.

JUNE 29, 1983: **Gallo** asks **Montagnier** for another sample of the French virus.

JULY 10, 1983: In a letter to **Montagnier**, **Gallo** expresses concern that **Essex** has now detected antibodies to HTLV in more than half the AIDS patients he tested, while Pasteur researchers are reporting only 20 percent of AIDS patients positive for antibodies to their virus. "Something is missing," he says.

JULY 18, 1983: **Montagnier** attends the monthly meeting of **Gallo's** AIDS task force, bringing a sample of LAV and photographs showing particles that look different from HTLV. **Gallo** tells the meeting HTLV-1 is a "very attractive" candidate for the cause of AIDS.

gin. But I was just being polite."

In December of 1983, Gallo finally sent his negative findings on HTLV-1 and AIDS to the Lancet. At first glance the paper looked like a refutation of what he had been saying for the last year about possible links between the leukemia virus and AIDS, but it was much more subtle than that. In addition to reporting the mostly negative antibody data, the Lancet paper encouraged speculation that the cause of AIDS might be an undiscovered near-relative of HTLV-1. "There is no need," the paper cautioned, "to assume that members of the HTLV family are limited to two strains."

Max Essex had recently found a slight genetic variation in the feline leukemia virus that he said turned it from a cancer virus into a cell-killer, and now Gallo was suggesting that the AIDS agent might be a similarly mutant form of HTLV-1. The "undiscovered relative" theory was attractive for a number of reasons. Among other things, Gallo had never been able to explain the absence of AIDS in Japan, nor how a virus that caused the uncontrolled multiplication of white blood cells could also be responsible for the disappearance of those same cells.

As it happened, researchers in Gallo's lab had recently discovered just such a minor variant of HTLV-1 in an American homosexual with AIDS. It was very closely related genetically to the leukemia virus, but different enough to justify a name of its own. Gallo called his newest virus HTLV-1B.

Because most of the differences in the "1B strain" followed the same pattern as those in the feline virus variant, it looked like exactly what Gallo had been predicting in the way of a cell-killing mutant.

In mid-January of 1984, Gallo dispatched a new article to Science reporting the isolation of HTLV-1B from a patient with AIDS. "We were very excited," recalled one of the scientists in Gallo's lab.

The 1B paper had not yet appeared when, in early February, 250 of the world's leading researchers gathered at Park City, Utah, for what would be the biggest scientific conference thus far devoted exclusively to AIDS. As at Cold Spring Harbor, Gallo would be the star. "You are the keynote speaker," Harvard's Jerry Groopman, one of the conference organizers, had written to him earlier. "You can speak for 45 minutes, 90 minutes, or two days if you would like."

According to notes taken by one scientist in the audience, Gallo began his keynote address by declaring that the "only candidate" for an AIDS virus was one of the HTLVs—maybe HTLV-1, possibly HTLV-1B. Whether they were leukemia viruses or AIDS viruses, Gallo said, they were all "one big family."

On the last day of the Park City meeting Gallo dictated a letter to Jay Levy, who had made some comments to a reporter that Gallo considered misinformed. Levy had suggested that the reporter ask Gallo why, if HTLV caused AIDS, there weren't many AIDS patients who also had leukemia. "I never said HTLV caused AIDS," Gallo wrote to Levy. Then he added, "HTLV itself, nonetheless, could still cause AIDS."

Luc Montagnier had had a hard time at Cold Spring Harbor, and David Klatzmann had been virtually ignored in New York City. Perhaps Jean-Claude Chermann, the chief of the Pasteur lab where the French virus had been isolated, would be more successful in Park City.

Chermann had known Gallo for nearly 20 years. The two men had been to each other's homes and dined with each other's families. But when they had last seen one another, in early October, 1983, at a meeting in Seillac, France, there had been an unaccustomed tension between them. "In October we know that we have the virus," Chermann recalled in his heavily accented English. "But everybody was saying that we were wrong."

In the belief that the scientific community was taking its cues from Gallo, Chermann said, he made one last appeal in Seillac to his old friend. "We took a bicycle ride," Chermann said, "and I said to Gallo, you know me for a long time. I can tell you we have the virus. I will not fight anymore with you. The next meeting will be in Park City, Utah. In February we tell you exactly how LAV is the cause of AIDS."

When Chermann's plane landed in Park City four months later, Gallo was at the airport. As Chermann recalled his conversation with Gallo during the ride into town, "He say, 'You know, Jean-Claude, you are invited to this meeting, but you cannot speak about LAV as a retrovirus.' He say, 'You don't know if it's a retrovirus,' and so on.

"I said, Bob, you know that I am working with retrovirus for 20 years. I will give exactly how we think about the virus. It was very difficult for me to speak. Jerry Groopman came and told Gallo, 'You have to let Jean-Claude speak.' "

Besides Groopman, the other Park City organizer was Michael Gottlieb, the UCLA immunologist who had reported the first cases of AIDS, in five homosexual men from Los Angeles, nearly three years before. The previous spring, a few weeks after the Pasteur group had published the BRU paper in Science, Gottlieb had heard Chermann and Klatzmann speak at a sparsely attended meeting in Naples.

It was Gottlieb who had discovered the most important clinical feature of AIDS patients, the depletion of their helper T-cells, and when he heard the news from Paris about a virus that killed those same cells he was electrified. "The words that come to mind are amazed, astonished," Gottlieb said. "I was sitting there hearing something that clicked, saying, these guys have found something important, these guys are on the right track." At breakfast the next morning, Gottlieb invited Chermann to Park City.

Park City is a ski resort in winter, and Gottlieb admits that "at these ski meetings, the pressure is to get the morning meeting done by noon so we can get out onto the slopes." Chermann had been given a place near the end of the morning program. At the last minute, Gottlieb recalled, Groopman and Gallo, who was chairing the session, added a Harvard researcher named William Haseltine to the program ahead of Chermann.

"I had been told by Groopman that Haseltine was only going to talk for 10 minutes," Gottlieb said. "Haseltine is still going at 30 minutes, and it looks like he's going for 45. I went to Groopman and I said, 'Hey, Jerry, this is your guy and he's cutting into Chermann's time.' Jerry got the chair's attention, and Gallo said something to Haseltine. Jerry told me later that Haseltine was livid."

When Chermann finally spoke, Gottlieb recalled, "he was a little flustered by the events, and his English isn't that great anyway. Jean-Claude—I love him—he's a great guy, but his presentation was a little discombobulated. But people were sitting there ready to go skiing and all of a sudden there were people saying, 'Hey, these guys have something.' These were people who hadn't read the Science paper; they hadn't heard the story."

Chermann provided an impressive summary of what the French had accomplished in less than a year: 10 isolates of their virus from patients with AIDS or pre-AIDS, the attraction of the virus for helper T-cells, even a new picture of the virus showing clearly that it didn't look anything like Gallo's leukemia virus. Chermann also presented new data showing that the Pasteur's AIDS blood test had found antibodies to the virus in nearly 40 percent of AIDS patients, and in almost 75 percent of those with pre-AIDS.

Those numbers were a quantum leap from the ones Montagnier had brought to Cold Spring Harbor, and following Chermann's talk a small group of American scientists paid a clandestine visit to his room. They wanted him to know, one of them recalled, that no matter what Gallo thought they had been convinced. As far as they were concerned, the cause of AIDS was the French virus called LAV.

The data from Paris were looking good, but in Gallo's lab there was trouble. Not long after the paper on the discovery of HTLV-1B had been submitted to Science, someone had discovered that the virus hadn't been isolated from an AIDS patient after all. It had come instead from a Zairean man named Elomata, one of the blood samples Jacques Leibowitch had brought Gallo from Paris. Elomata had died of adult T-cell leukemia, not AIDS, which meant that HTLV-1B was just a new variant of Gallo's leukemia virus.

"There was a mixup between the different DNAs," said one scientist who worked on HTLV-1B, explaining that someone in Gallo's lab had mistaken a 7 for a 1. Whatever occurred, overnight Gallo's AIDS virus candidate had vanished into the great, dark void of laboratory error. The paper on HTLV-1B that had been sent to Science never appeared, and it was not the only paper from Gallo's lab to disappear before publication during the long winter of 1984.

In early March, Gallo wrote the editor of the Lancet to ask that the paper submitted the previous December, the one showing that very low percentages of AIDS patients had antibodies to the leukemia virus, also be put on hold. His lab, Gallo said, had recently obtained "over 40 new virus isolates" from patients with AIDS and pre-AIDS, viruses that were "significantly" different from the leukemia virus or any of its known variants.

"My concern," Gallo wrote, "is that the mostly negative HTLV-1 data will be construed as negative to all HTLV. I need some time to think about the best way to present this to avoid confusion."

With the exception of the ill-fated HTLV-1B, Gallo hadn't mentioned anything about a new AIDS virus when he spoke at Park City less than a month before. But when the proceedings of the meeting were published several months later, they contained a paper by Gallo reporting the isolation of a new human retrovirus called HTLV-3 from "a large number" of AIDS patients.

"The week after the meeting," recalled Mike Gottlieb, who as one of the organizers was responsible for collecting and publishing the papers delivered at Park City, "someone in Gallo's lab called and told me they were going to send me a manuscript and to keep it quiet, to keep the information confidential.

"It's not kosher, but I had no sense at the time of what was about to happen. I don't want to look stupid or naive, but I certainly was naive. I did not read it carefully enough to appreciate the significance of the work or the political overtones." There "definitely" should have been a footnote to Gallo's paper pointing out that it was not delivered at the symposium, Gottlieb says, but there wasn't.

When the proceedings of the Cold Spring Harbor conference the previous September were published in the summer of 1984, they also lacked any indication that Gallo's introductory lecture had been rewritten. According to the new version, Gallo had obtained "over 50 isolates of a retrovirus from AIDS or pre-AIDS patients" called HTLV-3, which was "closely related to, but distinguishable from, HTLV-I and HTLV-II." Gallo's other Cold Spring Harbor paper, the one in which he had discussed "the possibility that HTLV plays an important role in the origin of AIDS," had vanished from the proceedings altogether.

If Gallo's discovery of HTLV-3 seemed to settle the cause of AIDS, it left open the question of Max Essex and his antibody test. If HTLV-3 was the cause of AIDS, then it wasn't HTLV-1. If it wasn't HTLV-1, then something was the matter with the Essex test. In March of 1984 the U.S. Patent Office agreed, rejecting the Harvard application for a patent on Essex's test on the ground that it was "inoperative and therefore lacks utility."

In other words, the Essex test didn't work. Or, rather, it worked too well. "I think Max is very lucky, or unlucky," said Cy Cabradilla, who tried to replicate the test for the Centers for Disease Control. "I took that procedure back to CDC, and we did get results that were very comparable." But when blood from people who didn't have AIDS was tested, Cabradilla said, "we were getting the same results."

Whatever the Essex test measured, it wasn't Gallo's leukemia virus. Gallo says now that although he had long suspected Essex's data were wrong, "in time I recognized how wrong. Did I know it then? Perhaps. Are you getting me on a weak point? Probably. I really don't know what he was detecting."

When Essex, who has never retracted his HTLV antibody papers, shared the Lasker prize with Gallo three years ago, the citation noted their "unique contributions to the understanding of AIDS." Last year, when Harvard created a university-wide office to coordinate its research on AIDS, Max Essex was the man it put in charge. Essex declined a request for an interview with The Tribune, citing "a heavy travel commitment and a tight schedule."

4 'Could you patent the sun?'

The afternoon of April 23, 1984, was one of those occasions relished by the federal government, a rare chance for the bureaucrats to go before the television cameras with their white hats on. As the medical writers filed into the cramped auditorium shortly after lunchtime, they were handed an eight-page release from the National Cancer Institute's press office. Soon they were listening to Margaret Heckler, the secretary of health and human services, announcing that "the probable cause of AIDS has been found."

It was, Heckler said, a new virus, and its discoverer was "our eminent Dr. Robert Gallo," chief of the National Cancer Institute's Laboratory of Tumor Cell Biology. Those reporters who wanted the scientific details were handed preprints of four articles by Gallo that would appear 10 days later in Science magazine. "Getting one paper in Science is a lot," Gallo said later. "Getting two is fantastic. Getting three was a record. We had four at one time."

The first article described the new virus, which Gallo had named HTLV-3, as the latest member of the human leukemia virus family on which he had built his scientific reputation. The second article reported the isolation of the virus from nearly 50 patients with AIDS or pre-AIDS, the third described its major proteins, and the last reported the invention of a blood test for antibodies to the virus.

Like many big stories in Washington Gallo's discovery began as a news leak, and before the story had played itself out it would reveal as much about the science of politics as about the politics of science. It broke on Monday, April 16, when the Wall Street Journal reported, "Speculation is mounting in the medical community that researchers soon will announce discovery of a new variation of human cancer virus that may cause acquired immune deficiency syndrome." Gallo's leukemia virus, the Journal noted, "has been suspected of causing AIDS since it was isolated in an AIDS victim last year."

Most scientists agree, and Gallo concurs, that the first word of a major discovery should come not at a news conference but in a scholarly article that has been subjected to prepublication scrutiny by independent experts in the field. "Science is after peer review," he told The Tribune. "You can't just go putting stuff in notebooks and handing them to reporters." The fact that his own landmark discovery was announced at a news conference, Gallo said, "wasn't my idea. It was as the result of a reporter that things hit the fan."

Gallo was referring to Martin Redfern, a science correspondent for the British Broadcasing Corp., whom Gallo has accused of stealing copies of the unpublished Science papers from his office. Redfern emphatically denies the accusation and gives a different version of events. A few days before the news conference, Redfern says, he stopped in Washington to interview Gallo about his leukemia virus research. Halfway through the conversation, Redfern said, Gallo told him that "we've just discovered the cause of AIDS."

"When the interview had finished," Redfern recalled, "he said, 'Would you like preprints of the papers?' To which I said, 'Dead right.' He asked one of his colleagues to get them out. The chap's eyes opened rather wide and he said, 'Are you sure? All four of the AIDS papers?' And Gallo said, 'Yes, I trust this man.' There were several people around who were a little surprised that he'd given me the story."

In a 1987 interview with the Dutch newspaper Financiel Dagblad, Gallo maintained that "after the interview, when I left my room for lunch, he took private documents from my desk."

Redfern says that he promised Gallo he would keep the story to himself unless it broke first somewhere else, and that he reported what he knew only after the leak had appeared in the Wall Street Journal. In fact, it was Gallo himself who first disclosed the existence of HTLV-3 a month before the Journal article appeared, in a speech in mid-March to a meeting of the French Association for Cancer Research in Marseille.

To the millions of Americans who watched the evening news and read the next morning's newspapers, however, Gallo's news conference seemed a genuinely historic moment. Three years ago AIDS hadn't even been recognized. Two years ago it didn't have a name, and now an American cancer researcher had found the cause.

AIDS was fast becoming a partisan issue, and behind all the self-congratulation there were unmistakable political overtones. With increasing frequency the Reagan administration was being accused, not just by homosexual groups but by scientists and some members of Congress, of not having done enough or spent enough, quickly enough, to gain a foothold in the battle against the disease.

But here was Secretary Heckler telling the critics they could thank the Reagan administration for the fact that the cause of AIDS had been found, and with it a test to screen the blood supply for contamination with the virus. A vaccine to protect the uninfected, she said, might be available within two years. Heckler's optimism about an AIDS vaccine was unfounded, and much of what was said that April afternoon would not bear up later under scrutiny.

Near the end of the news conference, a reporter asked Gallo when he had actually made his momentous discovery. When, precisely, had he isolated the AIDS virus? "When you see the papers published in Science," Gallo said, "you will see that we've been mass-producing it for six months. Okay?"

Six months before the news conference was late October of 1983. But the minutes of Gallo's AIDS task force meetings for November and December contain no indication that the AIDS virus had even been identified, much less mass-produced, by Gallo's lab. Instead, the minutes reflect a mounting concern among the task force members about the lack of any solid link between AIDS and Gallo's leukemia virus.

The question of just when Gallo's lab found the AIDS virus is further obscured by his assertion to The Tribune

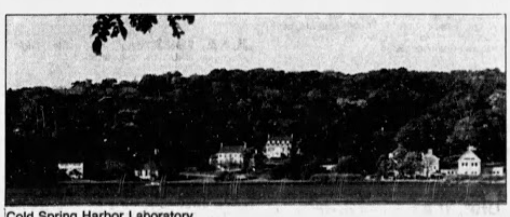
AUG. 4, 1983: Gallo and others conclude that **Charles Robinson** did not have mycosis fungoides but died of "a new form" of lymphoma very similar to ATL.

AUG. 15, 1983: Gallo receives a sample of **BRU's** serum from Paris. Same day, **Essex** sends a paper to Science reporting that hemophiliacs are also positive for antibodies to HTLV.

AUG. 26, 1983: The Pasteur group and collaborating French physicians send Nature magazine a paper reporting that LAV infects and kills helper T-cells, the same kind of cells whose disappearance causes an immune deficiency in AIDS patients. The paper, which provides the strongest link yet between the French virus and AIDS, is rejected.



Cold Spring Harbor Laboratory

SEPT. 14, 1983: A major conference on HTLV begins at Long Island's Cold Spring Harbor laboratory with an introduction by **Gallo**, who says he believes HTLV is involved in AIDS.

SEPT. 15, 1983: **Montagnier**, who is given only 20 minutes to speak, tells the conference his group has found LAV antibodies in nearly three-quarters of patients with pre-AIDS and in 20 percent with AIDS. Same day, Pasteur lawyers apply for a European patent on the LAV blood test used in the studies.

SEPT. 20, 1983: Gallo writes another scientist that he now has 11 isolates of HTLV "and related retroviruses" from AIDS patients.

SEPT. 22, 1983: A second shipment of LAV is delivered to **Gallo's** lab. **Mikulas Popovic, Gallo's** chief virologist, signs a receipt promising that it will not be used for commercial purposes. **Popovic** immediately begins trying to grow the virus and sends a small amount to **Matthew Gonda** in Frederick, Md., for observation under the electron microscope.

SEPT. 27, 1983: Gallo writes a German scientist that a genetic variant of HTLV is the "most likely" candidate for an AIDS virus, adding, "I have never seen the virus that **Luc Montagnier** has described." Same day, **Gallo's** assistants give him a copy of their unpublished paper reporting fewer than 10 percent of AIDS patients have antibodies to HTLV-1.

Continued from preceding page

that "in the month of January we had all essential data," and that by the time of the symposium in Park City in early February "we knew everything that we published."

According to Gallo's lab records, it was in mid-January that he sent to Science the paper reporting the discovery of HTLV-1B in an American homosexual with AIDS. It was during the Park City meeting that Gallo had admonished Jay Levy, the University of California virologist, that "HTLV itself" might be the cause of AIDS.

Gallo's records show, moreover, that some of the essential data contained in the four Science papers could not have existed until less than a month before the papers were submitted for publication at the end of March, and the discrepancies between the data in the records and the published articles suggest the haste with which they were assembled.

Three weeks before the news conference, Gallo flew to Paris to confer with the AIDS team at the Pasteur Institute. As Luc Montagnier remembers the meeting, Gallo told the French that he would soon be announcing his discovery of the cause of AIDS. "He said that he would have several papers published shortly in Science and he didn't know exactly how this would be announced," Montagnier said, "that perhaps a press conference would be done."

The French, who had been trying to persuade the scientific community for nearly a year that the virus they called LAV was the cause of AIDS, were taken aback. The day after Gallo's visit, they had published a paper in the Lancet, their first in a major journal in nearly a year, reporting the latest evidence linking their virus with AIDS.

According to Jean-Claude Chermann, in whose lab LAV had been discovered, Gallo assured the French that he thought his virus and theirs were the same and that he didn't intend to take any of the credit that rightfully belonged to the Pasteur Institute. After the news conference, Gallo telephoned Montagnier in Paris. "He said, 'It's over now,' " Montagnier recalled. " 'I mentioned your contribution and I think everything is fine.' "

Gallo has said repeatedly since then that he acknowledged at the news conference that the two viruses were the same. An official transcript of the news conference, however, does not contain such a statement. When a reporter asked Gallo whether the two viruses were the same, Gallo said, "It may in time be the same as what has been called LAV in a couple of publications," but he added that "I cannot say at this point whether the viruses are identical."

In that morning's Washington Post, Gallo had cautioned that "only time will tell" if the two viruses were the same. He was "astounded," he said, by the "hullabaloo" caused by "sour-grapes" comments from unnamed scientists "who seem to be threatened by my data." When the four Science papers were published 10 days later, one of them contained the assertion that "HTLV-III and LAV may be different."

Predictably, Gallo's comments caused consternation at the Pasteur. "He was just saying, we don't know if it be the same," Chermann said. "And that, scientifically for me, ethically and morally, was not acceptable." Chermann recalls that when he brought the matter up later, Gallo blamed his staff: "He say, 'I put all my people in the room and we discuss. At the end we ask, is the same or is not the same? And people say is not the same.' "

The question Gallo had left hanging—were the two viruses the same?—was not a trivial one for those engaged in the search for a vaccine and a cure. As Richard M. Krause, then-director of the National Institute of Allergies and Infectious Diseases, wrote in a memo to the head of NIH, "It is important to learn if HTLV-3 and LAV are one and the same virus, or are two somewhat different viruses each able to produce a syndrome that resembles AIDS."

According to records from Gallo's lab, experiments by his assistants had already produced evidence that his virus and the one from Paris were the same.

In the months before the news conference, Gallo's staff had begun a series of tests on several cell cultures in which they hoped the new AIDS virus was growing, mixing the cultures with blood serum known to contain antibodies to the AIDS virus. If the antibodies in the serum attached themselves to the cells, it meant the virus was present in the cultures.

Gallo's lab had several sources of serum from which to choose, including some from a hemophiliac with pre-AIDS identified as ET, and some from a laboratory rabbit that had been deliberately injected with the AIDS virus. According to Gallo's published papers, almost every one of the AIDS virus cultures showed a strong positive reaction to both the rabbit and ET.

Although it was not mentioned in any of his articles, Gallo had a third source of AIDS virus antibodies with which to test his cultures. In the summer of 1983, Luc Montagnier had sent Gallo a sample of blood serum from BRU, which experiments at the Pasteur had already shown was loaded with antibodies to the French virus—not surprising, since BRU was the source of the original French isolate.

When Gallo's assistants mixed BRU's serum with the cells where the AIDS virus was believed to be growing, the lab notes show, in some cases the reactions were more intense than with the serum from ET. If BRU had antibodies to Gallo's AIDS virus, then the Gallo virus and the French virus were almost certainly the same. But none of Gallo's Science articles reported that BRU's serum had even been used in the experiments, much less that the reactions had been positive.

As the controversy between Paris and Bethesda over who had been first to discover the AIDS virus began to generate heat, Gallo changed direction. Even if he and the French had isolated the same virus, he began to say, his lab had been first to develop a working blood test for the AIDS virus and first to prove that the virus was the cause of the disease.

According to Nature magazine, when Gallo and Montagnier shared the Lasker Prize in September of 1986 the news release, which had originally credited Montagnier with the discovery of the AIDS virus, was changed at the last minute because of objections from the American jurors to cite him for having found a virus that was "later shown to be the cause of AIDS."

The distinction is far from academic. Finding a new virus in a patient with a new disease, or even in several such patients, is not the same as discovering the cause of the disease. The new virus might be the cause, but so might some other virus still lurking in the background. To link a specific virus with a specific disease, it is necessary to show that everyone who has the disease is infected with the virus, by finding viral antibodies in the blood of large numbers of people who are sick. Before such a search could be mounted, however, there would have to be a blood test for AIDS. (See TEST, p. x.)

In the two centuries since Priestly and Lavoisier raced each other to discover oxygen, the desire to be first has helped push science forward. Nobels and Laskers have stepped up the pace. But there was much more than prizes and prestige riding on the development of a successful AIDS test.

Whether it was French or American, a test for AIDS would be a most welcome development from a public health standpoint. Although it had been clear for at least two years that AIDS was being spread through blood transfusions as well as sexual intercourse, there hadn't been any way to screen the blood supply.

As the number of people with AIDS grew, so did the market for such a test, and most of it was in the United States. Just to keep the domestic blood supply pure, the federal government estimated that 23 million tests would be needed each year, and that didn't take account of the growing demand from people in this country and abroad who wished to find out whether they had been infected.

The Reagan administration was much less interested in patent royalties than in the domestic and international political considerations of being first with an AIDS test. But for a nonprofit institution like the Pasteur that receives less than half its funding from the French government, the royalties from what has become a $175 million-a-year AIDS test market in the U.S. alone would pay for a great deal of research.

To the National Cancer Institute, stepping to the forefront of AIDS research could mean a welcome end to the long dry spell of budget increases that had followed the reverses of the government'a war on cancer. For Gallo and his senior assistants, an AIDS test patent would mean hundreds of thousands of dollars in royalty payments in addition to their government salaries.

By February of 1984 Gallo's lab had developed an AIDS blood test, called an ELISA, that is fundamentally the same as the test employed today by hospitals, clinics and blood banks around the world to guard the blood supply. As soon as it was ready, Gallo asked the Centers for Disease Control to send him a large number of blood samples from patients with AIDS and pre-AIDS with which he could prove its accuracy.

Among the more than 200 blood samples the CDC shipped to Bethesda on Feb. 27 were a number from men and women who didn't have AIDS and didn't belong to any of the groups most likely to get it. All the samples were "blind," labeled only with a code number that gave no indication of whether the donor was sick or well. If Gallo's ELISA could distinguish between them—if the sick donors had antibodies to his virus and the well donors didn't—it would prove not only that his blood test worked but also that his virus was the cause of AIDS.

A few weeks later the CDC gave Gallo the results. His ELISA had done so well that there was no doubt his virus was the cause of AIDS. But when Gallo arrived in Paris in early April to inform the French of the impending announcement of his discovery, he was met with a surprise. In the belief that the French should be given a chance to test their ELISA on the same blood samples, the CDC had shipped a second set to the Pasteur.

Among those at the Paris meeting was Donald Francis, the CDC epidemiologist in charge of ELISA testing. Francis, who has both a medical degree and a Harvard Ph.D. he earned in Max Essex's lab, had brought with an 11-page, single-spaced computer printout that contained the scores for both sides.

"We sat there in Jean-Claude Chermann's office with the printout, three or four fingers going down these columns, looking at the similarities and dissimilarities," Francis recalled. When they reached the bottom, it was clear that the French ELISA had scored as well as Gallo's. Both teams had gotten the right answer on 78 percent of the samples tested, but Gallo had marked many of his blood samples "plus-minus," scientific shorthand for "maybe it's there and maybe it's not."

"Gallo really cranked up the specificity on his test to make sure he wouldn't miss anything," Francis said, adding that Gallo had scored more than twice as many false positives as a result. When all the "plus-minuses" were changed to positives, Gallo scored 81 percent and the French, who had many fewer "plus-minuses," had 79 percent. Despite his slight margin in the corrected scores, two things were now obvious: Both the French virus and Gallo's were the cause of AIDS, and the French had an equally reliable test.

There had been considerable tension during the Paris meeting—at one point Gallo had insisted that Don Francis leave the room because he wasn't a practicing virologist—and that evening Chermann took everybody to the Paradis Latin, a glitzy supper club on the fringes of the Latin Quarter with a topless floorshow. According to Chermann, when he and Gallo found themselves in the men's room, Gallo suggested that perhaps the blood test results should be announced by himself and the Pasteur.

"We can do this together," Chermann recalls Gallo telling him. "We don't need CDC." Chermann was flabbergasted, but no more so than Francis, who remembers Gallo telling him the next morning at breakfast: "You and I can do this together. We don't need the French."

In the end, Gallo did it alone. At the news conference two weeks later he didn't mention that the French virus had passed the same test, and Gallo now hints that he mistrusted the CDC's results from the beginning. "I never stood over that code and went through it with them," Gallo told The Tribune. "How do I know and how do you know? It was in their hands."

The French were eager to publish the results of their performance in the CDC competition. Because the testing had been done in collaboration with Gallo, Montagnier said, the French felt the results should also be published jointly. "Enclosed is a draft of the comparative serology which we discussed last April in Paris," Francis wrote to Gallo in October, 1984. "Please send me comments, authors and corrections as soon as possible."

When Gallo replied two months later, his primary interest seemed to be in the apportionment of credit. "If LAV precedes HTLV-III in this paper as a title then I will be last author," he wrote to Francis. "If not, I don't care who the last author is. (One or the other Don, but not both for your friends abroad). If there is a problem for you then let's just forget the whole thing."

The results of the blood testing were never published. Two years later, when Gallo prepared a sworn statement recounting the history of his AIDS research, he maintained that at the time of the news conference in April of 1984, "my colleagues and I did not consider LAV and HTLV-III to be the same, or even substantially the same, virus. Quite clearly the data available to us indicated that the two viruses functioned differently and reacted differently."

More than 30 years ago, broadcaster Edward R. Murrow asked Jonas Salk who should own the rights to the polio vaccine that bears his name. "Well, the people, I would say," Salk replied. "There is no patent. Could you patent the sun?"

It is still not possible to patent the sun, or any of nature's original constituents. But it is possible to patent a useful rearrangement of nature, and when the Supreme Court ruled in 1980 that the patent and trademark laws could be applied to the products of genetic engineering—in that particular case, to a microbe that ingests petroleum and might be useful in cleaning up oil spills—the biotechnology industry was born.

On Sept. 15, 1983, as Luc Montagnier was announcing the Pasteur's initial ELISA results at Cold Spring Harbor, the institute's attorneys were in London filing an application for a patent on the Pasteur ELISA made with LAV. In early December, while Gallo was still trying to unravel the mysteries of HTLV-1B and the Essex test, the Pasteur filed an application for an American patent.

But as Gallo and Margaret Heckler stood before the television cameras in late April of 1984, the Pasteur no longer had the field to itself. A few hours before the news conference, the U.S. government filed an application of its own for a patent on the ELISA made with Gallo's AIDS virus, HTLV-3. The application included a sworn declaration in which Gallo stated that he was "the original, first and sole inventor" of the AIDS ELISA.

The stakes riding on the competing applications were enormous. If the American patent were granted to Pasteur, it meant no other AIDS test could be produced and sold in this country without paying royalties to the French. If the U.S. government's application prevailed, Pasteur would be shut out of the only market that really mattered.

In patent law priority is everything, and in the case of the AIDS test there didn't seem to be any question about who had finished first. Although Gallo later asserted in scientific articles that the first AIDS blood testing had been done in his lab, the Pasteur had been using its ELISA to test blood samples for months before Gallo even had a virus to test with.

The previous November, while Gallo was still deciding whether to publish the data showing that most AIDS patients weren't infected with his leukemia virus, the French were running the first controlled test of their ELISA with blood samples from the CDC. On the very day the CDC shipped blood samples to Gallo's lab, in fact, the Pasteur team was reporting the results of their ELISA tests in a French medical journal. But when the Gallo AIDS test patent was granted in May of 1985, the Pasteur's application was still gathering dust.

The French, Gallo said later, hadn't received the patent "because they didn't have a working test." In 1985, when the Pasteur Institute filed a formal challenge to the Gallo AIDS test patent, Gallo declared in a sworn statement that while he was "satisfied that HTLV-III had been proven to be the cause of AIDS. . . . I saw no evidence of this for LAV up through the allowance of the Gallo patent."

Such accusations greatly distress the French. "We had the test by the summer of 1983," Montagnier says. "The test was not as sensitive as it is now, so we missed more than half of the AIDS patients. But for people who were just healthy carriers it was OK. We could detect a very high proportion. It could have been used for blood supplies."

Montagnier wrote to the French Ministry of Health offering the ELISA to test the French blood supply and screen potential donors. "I got a nice answer but nothing was done," he said. "People did not believe. Even some of my French colleagues said, well, you have a new retrovirus. But why do you have to involve that retrovirus in AIDS? AIDS is caused by HTLV-1."

"We should have been able to produce the test for commercial use," Montagnier says. "It could have been done. Some time, perhaps a few months, could have been gained, if people had believed what we said. Some lives could have been saved."

When Gallo announced his AIDS virus in April of 1984, it had been more than eight months since the French had first sent a sample of their virus to Gallo's lab. But Gallo told the reporters he hadn't been able to compare his virus to theirs because the French hadn't sent enough to make such comparisons possible. "There could not be a definitive answer from the lack of material that was sent to us," Gallo said. "That's what's been the delay." In a letter to Chermann that summer, Gallo reaffirmed that "the material you sent to us was inadequate for comparative studies."

Gallo maintains that there was no virus in the small vial of frozen liquid that Montagnier had brought to Bethesda in July of 1983. According to Montagnier, when he delivered the vial to Gallo's home Gallo put it in the vegetable crisper of the family refrigerator where it eventually thawed, allowing the virus to die.

Whatever happened to the July shipment, a week after the confrontation between Gallo and Montagnier at Cold Spring Harbor the following September a second shipment of virus was on the way from Paris to Bethesda. Now that the French had applied for a patent on their virus, they asked Gallo to agree in writing that the sample would not be used for any commercial or industrial purpose.

On Sept. 22, 1983, the day the second shipment arrived in Bethesda, Mikulas Popovic, Gallo's chief virologist, began trying to grow it in the same kind of helper T-cells from fresh umbilical cord blood in which the French had first isolated the virus from BRU.

Although Chermann recalls Gallo telling him in Park City that "nobody believes your virus is a retrovirus," Gallo's lab records show that the French virus was kept alive in the cord blood culture for several weeks while Popovic established two critical facts: that the French had discovered a human retrovirus, and that it wasn't Gallo's leukemia virus.

According to the records, Gallo's lab also had visual evidence that the French virus was unique. On the same day the cord blood cultures were set up, Popovic sent a sample of the virus to Gonda's electron microscope lab in Frederick. Within a few days Gonda reported that the electron microscope showed a particle that looked like a lentivirus.

Growing the AIDS virus in fresh white blood cells, as both Popovic and the French had done, is not the only way of keeping it "alive." A more efficient method is to put the virus in a self-propagating culture known as a permanent cell line, but Gallo has repeatedly asserted that his lab was unable to grow the French virus successfully in such a cell line. (See LINE, p. x.)

The virus, he wrote in the first of the four Science articles published in May, 1984, "has not yet been transmitted to a permanently growing cell line for true isolation and therefore has been difficult to obtain in quantity." According to a 1986 memo from Popovic to Gallo, however, in December of 1983 the French AIDS virus was "successfully transmitted" into a permanent cell line, called Ti7.4, which "yielded reproducible but low-level LAV."

In his conversation with The Tribune, Gallo said that the laboratory comparisons between his AIDS virus and the one from Paris had never been made, and that his failure to make them was "the one thing that I regret. It is true

Popovic memo about LAV

Final paragraph from memo dated Aug. 19, 1985, from Mikulas Popovic to Robert Gallo and associate NCI director Peter Fischinger, reporting that the French AIDS virus was grown successfully in Gallo's lab and found to be the same as Gallo's AIDS virus, HTLV-3.

By December 1983 we had prepared specific reagents against HTLV-III. We then transmitted LAV to a cell line developed at M.D. Anderson Hospital known as TI 7.4. This T-cell line yielded reproducible but low-level LAV. We later tested our reagents against this cell line and eventually showed that LAV and HTLV-III had cross-reactive major proteins. We concluded that they could be related viruses or the same general subtype. By January-February 1984 others in our group showed that more than 90% of AIDS sera reacted with HTLV-III specific proteins. We never "scaled-up" LAV for comparable testing but noted that as late as October-November 1983 Montagnier found only 20% AIDS sera reacted with LAV.

Mika Popovic, M.D.

OCT. 3, 1983: **Gonda** tells **Popovic** he has photographed the French virus and it appears to be a lentivirus, a slow-acting retrovirus of a different category than HTLV.

OCT. 6, 1983: **Popovic** determines LAV does not react with antibodies to HTLV, indicating the French have discovered a new human retrovirus.

OCT. 18, 1983: **James Hoxie** sends **Gallo** a blood sample from **RF**, a Haitian immigrant who is dying of AIDS in Philadelphia.

OCT. 19, 1983: A Long Island physician sends **Gallo** malignant tumor cells taken from a 57-year-old carpet salesman infected with the AIDS virus from a blood transfusion.

OCT. 24, 1983: **Gallo's** assistants use LAV to infect five permanent T-cell lines, including HUT78 and Ti7.4.

OCT. 26, 1983: Work is completed on HTLV-1B, a genetic variant of HTLV that Gallo believes may be the cause of AIDS.

NOVEMBER, 1983: The NCI AIDS task force learns that experiments by one of its own members show only 1 of 59 AIDS patients has antibodies to HTLV. The group says "the very low" percentages are "a continuing problem."

NOV. 10, 1983: **Popovic's** notes appear to show that the French virus is reproducing in Ti7.4 and HUT78. The next day, he apparently renames the two cultures HUT78/V and Ti7.4/V.

NOV. 11, 1983: **Gallo** is awarded the American Cancer Society's Medal of Honor.

NOV. 15, 1983: **Popovic** begins the isolation of HTLV-3B by pooling cells from the Long Island carpet salesman and two other patients in HUT78. Same day, he sends **Gonda** samples of the HUT78 and Ti7.4 cultures in which LAV is growing.

NOV. 16, 1983: French immunologist **David Klatzmann** presents the data from the paper rejected by Nature to a meeting of the New York Academy of Sciences. He is virtually ignored.

NOV. 21, 1983: **Popovic's** notes show HUT78/V and Ti7.4/V are "OK," an apparent indication that the French virus continues to grow in both lines.

NOV. 22, 1983: **Popovic's** notes contain the cryptic entry "HUT78/V; Ti7.4/V = MOV." Same day, he adds more material from the initial three patients to his pooled HUT78 culture. In Paris, Pasteur researchers make their first successful infection of a permanent B-cell line with LAV.

NOV. 28, 1983: The University of California's **Jay Levy** says he has isolated the retrovirus he calls ARV from a San Francisco homosexual with AIDS.

NOV. 29, 1983: According to **Popovic's** notes, a new cell line called Htu4, derived from HUT78, is infected with the virus **Popovic** now calls "MOV."

DEC. 5, 1983: Pasteur applies for a U.S. patent on its LAV blood antibody test. **Popovic** sends the virus called MOV to **M.G. Sarngadharan**, the Gallo assistant in charge of developing a blood test for AIDS.

Gallo and then-Health and Human Services Secretary Margaret Heckler at the news conference announcing isolation of the virus.

Continued from preceding page

that we had reagents before submitting our papers to have analyzed Montagnier's virus, and to have concluded in those papers that his and ours were essentially the same virus."

The Popovic memos state, however, that the comparisons Gallo mentioned were carried out. The infected Ti7.4 cell line, one memo says, was "used for comparative studies" with the Gallo AIDS virus. "We later tested our reagents against this cell line," the memo maintains, "and eventually showed that LAV and HTLV-III had cross-reactive major proteins." Popovic declined to be interviewed.

Neither Popovic's memos nor the portions of his laboratory notes made public under the Freedom of Information Act contain the data produced by the experiments with the French virus to which the memos refer. According to one memo, however, the initial confirmation that the French virus was growing in the Ti7.4 cell line was obtained on Dec. 14, 1983—the same day Gonda informed Popovic in writing that the virus in that cell line was producing lentivirus particles.

It was also on Dec. 14 that Gallo wrote a letter to a French scientist, not one affiliated with the Pasteur, bringing him up to date on his AIDS virus research. Although his lab had now found antibodies to the human leukemia virus in a number of AIDS patients, Gallo wrote, "We still have not seen the Montagnier group's type of virus in a patient here, nor to my knowledge has anyone else."

The Popovic memos do not appear to contain some of the most important details of his AIDS virus research. According to the memos, the French virus was put into the Ti7.4 cell line in mid-December of 1983—*after* the Gallo AIDS virus had been isolated and used to make the rabbit antibody and the blood test for AIDS. But the lab notes on which the memos are based appear to show that the French virus actually began growing in Ti7.4 on Oct. 24, 1983—three weeks *before* the isolation of the Gallo AIDS virus was begun.

Nor do the Popovic memos mention that Ti7.4 was not the only cell line in which he succeeded in growing the French virus. According to Gallo's lab records, a second T-cell line called HUT78 was also successfully infected with the French virus on Oct. 24.

What ultimately became of the French AIDS virus Popovic was growing in the two cell lines is unclear from his laboratory notes. Popovic later maintained in an interview with Science magazine that the cells in both lines had died after two or three weeks. None of Gallo's lab records that were made public mention the death of either culture, and notes from a different section of Gallo's lab appear to show more than 70 references to further experiments involving LAV in the late winter and spring of 1984.

In January, the notes show, LAV was being compared genetically with the leukemia virus that Gallo incorrectly believed to be the cause of AIDS. In February, DNA was being obtained from "LAV producer human cells." Notes from March and April appear to reflect the use of LAV in several genetic engineering experiments.

Gallo says the handwritten notations are not references to the French virus, but rather a generic designation for the AIDS virus employed by some of his assistants before the name HTLV-3 was adopted in the four Science papers. "We didn't know what to call it," Gallo told The Tribune. "Until we published those papers we had a million and one names."

The lab notes, however, show that the Ti7.4 cell line and other cultures that were clearly infected with the French virus were called LAV, while those infected with other viruses were given different names. The notes also contain several references to LAV that bear dates later than March 30, the day the four papers were submitted to Science.

The fact that Gallo's lab had assembled persuasive evidence months before his news conference that the AIDS virus from Paris was the same as his own was never disclosed to his fellow scientists, to the press or to the public, much less to the researchers at Pasteur.

After the Park City meeting in February of 1984, Chermann was invited to Bethesda to give a talk on LAV. Popovic was in the audience. "Afterward I said to Mika, we send you twice or three times the virus," Chermann recalled. "We need to know if you are replicating or not the virus. And he told me—you know, with his pipe like this—'I cannot speak. Only the boss can speak.' "

5 'Only because there are so many'

In the summer of 1984, the race was over and Robert Gallo had won. With the publication of Gallo's unprecedented four papers in a single issue of Science, the medical community had accepted what the French had been saying for over a year: that AIDS was caused by a new human retrovirus. Now that there was a virus to study, the long march toward a vaccine and a cure could begin.

Still, there were some stray ends that needed tying up. In August, San Francisco's Jay Levy published a paper in Science reporting the isolation of the AIDS virus he called ARV. Levy said he had actually found ARV the previous November, making him the first American to have isolated the AIDS virus. But he was the second American to publish, and that made him an also-ran.

Gallo had a couple loose ends of his own. One was the paper he had withheld from the Lancet in March, reporting that most AIDS patients weren't infected with the human leukemia virus. Another was his paper on HTLV-1B, which had now been rewritten to identify the source of the virus as "an African patient with adult T-cell leukemia." But nobody outside Gallo's lab knew about the mixup with HTLV-1B or that the leukemia virus antibody paper had been held up for many months, and when those papers finally appeared in print hardly anybody noticed.

The only cloud on the horizon that summer was a paper in the Lancet by Robin Weiss and his colleagues in London, who had tested nearly 2,000 Britons for antibodies to the Gallo and French viruses. Half, who weren't at risk for AIDS, had tested negative. Almost all the others, who either had AIDS or were at risk, were positive. Since the CDC competition hadn't ever been published, the Weiss paper represented the first large-scale blood test results for the French virus.

What made the paper even more significant was the way the tests had been conducted. The first virus tested was LAV. But when HTLV-3 was exposed to the LAV-positive samples, all the antibodies had been "sopped up" by the French virus—a clear indication that the two AIDS viruses were the same.

Everyone who had anything to do with AIDS that summer was reading Gallo's papers, and many of them wanted a sample of his new virus to work with. If science was going to find a vaccine or a cure, scientists needed to study the virus that was now officially responsible for having claimed thousands of American lives.

There is a gentlemen's agreement in science that a researcher who claims to have isolated a new virus is obliged to send a sample to anyone who asks. The French, for example, had begun sending their virus to Gallo almost from the day it was discovered. The stated reason for such professional comity is to further the dissemination of scientific information; the unspoken one is to discourage cheating. And while some scientists are quicker than others to honor the unspoken agreement, it is NIH policy that cells, viruses and other materials discovered in its laboratories must be made available "to the field."

Early in April of 1984, workers at the cancer institute's Frederick, Md., facility, which occupies part of the Army's old biological warfare center at Fort Detrick, had begun growing the Gallo virus in enormous quantities. The day before Gallo's papers were published in Science, he wrote to several of his closest colleagues, including Max Essex at Harvard, to say that samples of his new AIDS virus would be available to them within a few weeks—on condition Gallo's name be included as an author on whatever papers they might publish later. But when a letter arrived from Jay Levy asking Gallo for a sample of HTLV-3, it was ignored. "I never got any virus from Bob," Levy says.

"Gallo was being very careful about who he gave the virus to," recalled W. Gerard Robey, who collaborated with Gallo while at Frederick and is now with Abbott Laboratories in Chicago. "He didn't want to give it to everybody and be scooped on half the interesting work."

Among those who had the most problems obtaining the Gallo virus were Donald Francis and his crew at the Centers for Disease Control. Although the CDC and NIH are sister agencies under the umbrella of the federal Public Health Service, there had never been much love lost between the two, and the tension between Francis's lab and Gallo's was especially thick. The CDC's decision to send blood samples to Paris for testing hadn't helped, and neither had the defection to Atlanta of one of Gallo's top assistants, V.S. "Kaly" Kalyanaraman.

"CDC was starting to be a big retrovirology center," recalled Jean-Claude Chermann. "It took Kaly, and some other scientists. Don't forget that the CDC had a lot of money for AIDS. At this time CDC was very important."

What appeared to bother Gallo most was the CDC's collaboration with the French. Don Francis's people had been growing the French virus in Atlanta for some time, and they insisted on referring to the AIDS virus in their papers by its French name, LAV. "I am puzzled," Gallo wrote to a senior CDC official, "by the continual use of LAV. As we have discussed periodically, the generic designation of the virus is HTLV-III/LAV."

According to Berge Hampar, then the general manager of the Frederick facility, while Max Essex and a few other researchers were given "tons of virus for free," the cancer institute charged the CDC $75 a liter. "The CDC actually had to open an account at Frederick," Hampar said. "Isn't that amazing?" Before Gallo would agree to give the CDC his new virus at any price, he made officials there sign a written promise not to compare it genetically with any other AIDS virus they might have growing in their lab.

The year 1983 had been a busy one for Gallo, and 1984 was busier still. When Gallo received the coveted General Motors cancer prize in early June, the citation was read by Robin Weiss, who recalls pointing out that Gallo had "published more papers during the previous year that I had in my entire career."

In between lectures and awards, Gallo continued to press the case for making the AIDS virus the newest member of his leukemia virus family. When the government applied for the patent on Gallo's AIDS test, it asserted that "the biological properties" of the AIDS virus proved that it was "a member of the HTLV family."

In scientific articles and interviews, Gallo elaborated on his rationale for making the AIDS virus the third HTLV. Both the AIDS virus and the other HTLVs were retroviruses, Gallo said, and both preferred to infect helper T-cells. Both viruses had core proteins that were the same size, he said, and their reverse transcriptases, the enzymes they used to reproduce themselves, had the same molecular weight. Both viruses, Gallo said, had a shared sequence of amino acids in the proteins that formed the outer envelopes that protected them when they were outside the cell.

Another of Gallo's arguments was that the leukemia virus and the AIDS virus had probably originated in Africa, and considering the number of AIDS cases there it seemed reasonable that AIDS had its beginnings somewhere on that continent. There wasn't very much adult T-cell leukemia in Africa, however—almost all the known cases had been found in the fishing villages of southwestern Japan—and there was virtually no AIDS in Japan.

Gallo set out to construct an epidemiological bridge between those two very different and distant societies, suggesting that the 16th Century Portuguese explorers who stopped in Japan might have brought with them African slaves or monkeys infected with a virus that eventually evolved into HTLV-1. In a letter to the British journal Nature, Gallo even maintained that the Japanese word for monkey, *amakawa*, was "derived from the Portuguese word macaco also meaning monkey."

When Yorio Hinuma, the Kyoto University virologist who with Isao Miyoshi had established the link between HTLV-1 and T-cell leukemia, heard about Gallo's hypothesis, he wrote his own letter to Nature. Hinuma cited evidence "that HTLV-1 was already present in aboriginal Japanese in pre-historic times." The Japanese word for monkey, Hinuma noted, was not *amakawa,* but *saru.*

The Pasteur's AIDS research group had known from the moment it discovered LAV that it bore no more than a superficial relationship to HTLV-1, and they had demonstrated many of the dissimilarities in their research. But Gallo kept insisting they were wrong.

"The virus, you explained to us, was not related to HTLV," he wrote to Jean-Claude Chermann in July. "We now know that it is related to HTLV-I and clearly belongs to that virus family." In an interview with the BBC a few weeks earlier Gallo went even farther, asserting that his lab had found genetic similarities between the AIDS virus and "the whole genome" of the leukemia virus.

In August of 1984, Gallo published a paper in Science that appeared to contain the first hard evidence to back up his assertions about the similarities between the AIDS virus and HTLV-1. Using a technique called hybridization analysis, which measures the degree to which two strands of DNA will adhere to each other biochemically and are thus alike, sections of the leukemia virus DNA had been found to have the same genetic composition as the AIDS virus DNA.

"The present data," the paper concluded, "support our proposal that this virus should be classified within the HTLV family." In November, Gallo published another paper endorsing the conclusions in his August paper. In a third paper published in December, he termed the genetic similarities between the AIDS and leukemia viruses "significant."

The day before the third paper appeared, dozens of biologists from around the world gathered in Wilson Hall on the tree-lined campus of the National Institutes of Health. They

Breeding ground for killer AIDS virus: Cancer in a jar

Human beings are really not much more than a collection of different kinds of cells: skin cells, blood cells, heart muscle cells, hair-forming cells and thousands of others, each providing some aspect of the body's structure and function. As the body grows or ages or repairs damage to itself, new tissue is formed by the division of existing cells.

The process of cell division can also be induced in the laboratory, by placing cells in a culture that contains the biochemicals and nutrients they need to live and grow. No normal cell will go on multiplying endlessly outside the human body. A skin cell may produce perhaps 50 generations before it dies, other kinds as few as a dozen. The exception is the cancer cell. Cancer, by definition, is the uncontrolled multiplication of a cell, and under the right laboratory conditions human cancer cells will continue to reproduce forever.

The type of cell the AIDS virus prefers to infect is a white blood cell called the helper T-cell, a key component of the human immune system whose role is to direct companion immune system cells, called B-cells, in the production of antibodies designed to kill viruses, bacteria or other invaders. Because the AIDS virus ultimately kills the T-cells it infects, when all the infected T-cells are dead the virus will also stop reproducing. To keep the AIDS virus replicating in the laboratory, it must either be fed a continuous supply of fresh T-cells or placed in culture with a collection of cancerous T-cells that are continuously reproducing on their own, the laboratory equivalent of cancer in a jar.

When a leukemic T-cell line is exposed to particles of the AIDS virus, the particles attach themselves to a particular protein, known as CD4, on the surface of the cells. Using the CD4 protein as a kind of portal, the AIDS virus deposits its genetic material—a single strand of RNA—in the interior of the cell. Once inside, the enzyme called reverse transcriptase begins making virtual carbon copies of the viral RNA in the form of its genetic cousin, DNA. This "proviral" DNA then inserts itself into the much longer strand of DNA that occupies the center of every human cell and contains the individual's complete genetic code.

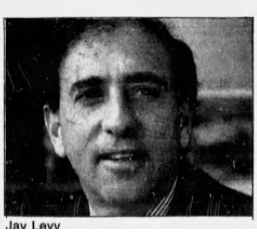
When, through a series of complicated internal and external events, the viral DNA is activated inside the T-cell, it produces new virus particles that burst forth from the occupied cell in search of new T-cells to infect. At the same time, the virus-infected T-cells often begin to divide and multiply. Because each new cell retains a copy of the virus's DNA and thus the ability to produce new particles of virus, the amount of virus in a patient's system—or in an infected T-cell line in a laboratory—can increase very rapidly.

Sooner or later, most AIDS-infected T-cells will be killed by the replicating virus, which does irreversible damage to the cell. However, some leukemic T-cell lines are resistant to the cell-killing effects of the virus. A few lines even seem to be immune, their infected cells apparently capable of surviving and dividing forever while providing a limitless source of virus for scientists to study.

DEC. 12, 1983: **Gallo** sends a paper to Science reporting that the Essex test is probably measuring antibodies to a protein from HTLV itself rather than a hybrid produced by an infected cell.

DEC. 13, 1983: A rabbit injected by **Samgadharan** with the AIDS virus begins producing antibodies that can be used to verify the presence of the virus in human cells.

DEC. 14, 1983: **Gonda** reports observing the AIDS virus in the HUT78 and Ti7.4 cultures in which LAV is growing. **Popovic** confirms LAV is growing in the Ti7.4 cell line. Same day, **Gallo** tells a French scientist, "We still have not seen the Montagnier group's virus in a patient here, nor to my knowledge has anyone else."



Jay Levy

DEC. 16, 1983: **Gallo** sends the Lancet his manuscript reporting fewer than 10 percent of AIDS patients have antibodies to HTLV.

DEC. 20, 1983: At its December meeting, the AIDS task force agrees that whether the Essex test is measuring antibodies to a viral or a cellular protein is now "a major question."

JAN. 2, 1984: **Popovic** sends more MOV to **Samgadharan.** Same day, he adds material from seven new patients to his pooled virus culture, now called "HTJV pool." His notes contain two other entries: "Sarang serolog. O.K.!!!" and

JAN. 6, 1984: The first AIDS virus antibody tests are performed in Gallo's lab on blood samples from patients with AIDS and pre-AIDS.

JAN. 10, 1984: **RF's** cells test negative for reverse transcriptase. **Gallo** tells a colleague that HTLV remains a leading candidate for the cause of AIDS.

JAN. 13, 1984: **Gallo** writes a German researcher that "we now have 18 isolates" of HTLV from AIDS patients, and that "it has become somewhat more likely that HTLV may be involved" in AIDS. He adds that the Essex test, which he had "worried" might be picking up antibody to a cellular protein, is measuring antibody

JAN. 18, 1984: **Gonda** reports that cells from **RF** and patients identified as **LS** and **BK** are all negative for virus. Same day, **Gallo** sends Science a paper reporting the isolation of HTLV-1B from a homosexual with AIDS.

JAN. 19, 1984: According to Gallo laboratory notes, the first experiments are begun in which "LAV" is genetically compared with HTLV-1 and HTLV-2.

JAN. 25, 1984: **Popovic** subdivides the HUT78 cell line, which he now calls HT, into 41

were there partly for the reasons that scientists have always gone to scientific meetings—to see old friends, exchange gossip in the corridors and listen to one another talk—and partly because this meeting offered a special attraction.

In biology the topic of the moment was AIDS, and the group that had assembled that morning in Bethesda could fairly be considered the illuminati of AIDS research. Max Essex and William Haseltine had come down from Harvard. Hilary Koprowski from the Wistar Institute in Philadelphia was there, and so was the grand old man of retrovirology, Ludwik Gross. Once again, however, the star was Gallo, whose discovery of HTLV-3 had brought him almost instant recognition as this country's foremost AIDS researcher.

It was a critical time for AIDS research, as scientists in the U.S. and abroad began to gain their first detailed understanding of the mechanics of the virus that was now killing hemophiliacs, transfusion patients and intravenous drug users as well as homosexuals. Gallo had been chosen to deliver the symposium's opening lecture, and he used the occasion to repeat the many similarities between the AIDS virus and his leukemia virus. So far, the two viruses had been compared only by indirect methods. The only sure way to determine how related they really were was to unravel their DNAs and compare them side by side.

The genetic sequence of the leukemia virus had been worked out by scientists in Japan the year before, and an intensive effort to sequence the Gallo AIDS virus had been underway for months, by researchers in the labs of Gallo, Haseltine and two private companies. "There were 19 of us involved," recalled Lee Ratner, who coordinated the effort from Gallo's lab, "and we worked our tails off for three to four months."

On the other side of the Atlantic, the Pasteur Institute had put together a team of five young scientists to break the genetic code of LAV. Unlike Gallo, they had no stake in whether the AIDS virus was a member of the HTLV family or not, and they had been saying for months that it wasn't. The real value of the AIDS virus sequence was that, once in hand, it would lay open the secrets of how the virus worked—and, perhaps, how it could be made not to work. The Pasteur group had found the virus a year before Gallo, but they were only slightly ahead in the race to decode its DNA.

Before the virus could be sequenced, its DNA had to be cloned—extracted from an infected T-cell and then copied millions of times by inserting it into a bacterium, called E. coli, that is the biological equivalent of a photocopying machine. The reason for the delay in Paris had been the difficulty encountered by the Pasteur's AIDS group in finding someone who wanted to do the cloning.

Ordinarily, the molecular biologists would have leapt to take part in a historic scientific event. But it wasn't yet clear that the project would be historic, and none of them wanted to risk spending months cloning a virus that might not be the cause of AIDS. "At this time nobody was believing us," Chermann recalled. "Pasteur was not believing us, and we were fighting against the Americans."

Chermann's lab was near the institute's computer center, a place where the molecular biologists tended to congregate, and to get there they had to cross his corridor. "I tried to stop some people to say, could you help us to clone," Chermann recalled. "If one had taken the bet, the virus would have been cloned and sequenced before the announcement of HTLV-3."

In the end he and Montagnier persuaded Simon Wain-Hobson, an Oxford-educated British expatriate who was working on the virus that causes hepatitis-B and teaching gene-cloning courses on the side. "Montagnier had asked a number of people on the staff if they wanted to do it, and many people said no," Wain-Hobson recalled. "He and I discussed it for a long time and perhaps we should have got going earlier, but I must confess that I was terribly unimpressed at the time. I said, 'Well I've got a few things to finish off and I'll start as soon as I can.' If he'd made a more convincing case I'd probably have started a bit earlier."

Montagnier also recruited two graduate students from the department of molecular biology, Marc Alizon and Pierre Sonigo. Once the cloning was done, the genetic sequence followed in relatively short order. "It was all over by early November," Wain-Hobson recalled. "We worked in shifts. It took us longer to write the paper than it took to do the sequence, because we're terrible at writing. We tried to make a nice paper of it."

By chance, Montagnier had been invited to speak at the NIH symposium in December, 1984, and as soon as the French sequence was finished he telephoned the symposium's organizer, Samuel Broder, to ask that Wain-Hobson also be allowed to speak. The French, Montagnier told Broder, had data "of great importance" to present, but he didn't say exactly what it was.

When Broder, who has since become the cancer institute's director, agreed, Wain-Hobson and Montagnier began to have second thoughts about showing their genetic sequence on Gallo's turf. If they didn't bring their sequence and Gallo presented his, Wain-Hobson remembers thinking, it would look as though the French were behind. But relations between Gallo and the French had deteriorated so much, Wain-Hobson said, that he wasn't sure what might happen to his data. In the end they decided not to show the sequence itself, but to present instead a "map" of the virus's principal genes, those regions of its DNA that contained the instructions for manufacturing its principal proteins.

Gallo's opening paper was followed by one from Max Essex and another from Gallo's chief molecular biologist, Flossie Wong-Staal. Wain-Hobson had been given only 10 minutes to speak, and when his turn came he didn't waste words. He began by questioning Gallo's published data showing similarities between the AIDS virus and the leukemia virus, and ended by unveiling his genetic map.

Several of those who were present remember the auditorium falling quiet as Wain-Hobson's slide flashed on the screen. According to the French gene map, the AIDS virus and Gallo's leukemia virus were hardly alike. The leukemia virus had only four genes; the AIDS virus had at least five, and there were important differences in their size and placement that made the AIDS virus the most complex human retrovirus yet seen.

The first two genes in the AIDS virus—"gag," which contains the genetic code for its core proteins, and "pol," for the reverse transcriptase—were about the same size and in the same place as in the leukemia virus. But the ends of gag and pol overlapped, and the French AIDS virus had a short third gene called "Q" that the leukemia virus was missing.

Farther down the sequence the real differences began to emerge. The fourth gene in the AIDS virus was "env," the gene that contained the code for the proteins that formed its outer envelope. The leukemia virus had an envelope gene too, but it was only about half as long. And the leukemia virus didn't have anything resembling the fifth gene, "F," that the French had found behind the AIDS virus's envelope.

As soon as Wain-Hobson finished speaking, several members of the Gallo sequencing group left the auditorium. The exodus was led by Haseltine, Gallo's longtime associate from Harvard and a key member of the team that, less than a week before, had finished sequencing the Gallo AIDS virus.

"I remember Bill stomping out of there with a contingent of people," said the CDC's Cy Cabradilla, who was in the audience that day. "I also remember him grabbing people and saying, 'No, no, his sequence is wrong. We've got the right sequence.' Bill Haseltine was very upset. Molecular biologist, cloner, sequencer, supposed to be a top gun, and here he got upstaged by the French."

When it was time for questions the Gallo group filed back to their seats. There were one or two half-hearted queries for some of the other speakers but no questions for Wain-Hobson. One member of the audience remembers thinking that everyone was waiting for Gallo to fire the first shot. If they were, he didn't disappoint them.

"Gallo walked to the microphone," recalled one scientist who was there, "and he said, 'I have a question for Dr. Wain-Hobson.' But he didn't ask a question, he made a speech. He talked for more than 10 minutes."

When Gallo finished, Wain-Hobson recalled, it was with a question. "Why," Gallo wanted to know, "do you stress the differences between HTLV-1 and HTLV-3?"

"Only because there are so many," Wain-Hobson replied.

Gallo now says he cannot recall attending the symposium. "I don't think anybody in our lab went to it," he said. "Who went? I was there?" But Gallo was there, and in the space of 10 minutes he had seen his arguments for the similarities between the AIDS virus and his leukemia virus demolished by his rivals from Paris.

"The people from Gallo's camp couldn't believe it," said Cabradilla, who was working on the sequence of another AIDS virus clone. "They were shocked. This small band of molecular biologists out of the Pasteur Institute had just beaten these guys from NCI and Harvard. Other groups, myself included, were saying, hey, good job."

No one outside the Gallo group will ever know for sure what the Gallo gene map of the AIDS virus looked like that day, because neither Gallo nor his associates presented any of their data at the symposium. But one member of another group that was working feverishly to finish the sequence of Jay Levy's AIDS virus recalls talking to a member of Gallo's staff after the meeting broke up. "I got the distinct impression that Simon Wain-Hobson had the story," the scientist said, "and that everyone else, including us, was close but behind."

Constructing a gene map from a DNA sequence can be compared to translating poetry from a foreign language. The poet's thrust may be obvious, but the elegance of the finished translation will turn on words that can be interpreted in more than one way. For a multitude of reasons, it is possible for two scientists to look at the same DNA sequence and disagree about where a gene begins and ends, or even whether it exists at all.

According to several members of the Gallo group, one of their disagreements with the French was over whether the fifth gene shown in Wain-Hobson's map was a real gene or a mirage. Because the leukemia virus didn't have five genes, the prevailing opinion in Gallo's camp was that the AIDS virus probably didn't either, and that what looked like a fifth gene was simply an error in translation. "Nobody was believing that it was a functional gene," said Nancy Chang, one of the Gallo sequencers. "We thought maybe it was a sequencing error, or not really anything significant."

In late January of 1985, spread across several pages, Nature published the Gallo lab's genetic sequence of the AIDS virus, row after row of a's, c's, g's and t's, more than 9,200 in all. Gallo called the sequence "a significant step forward in understanding how the virus works." AIDS researchers, Haseltine said, could now "see the face of the enemy." But the face drawn by Gallo and Haseltine was that of the wrong enemy. Unlike the French, they were still fighting the last war.

The Gallo sequence paper also contained a gene map, and its first two genes, pol and gag, looked exactly like those in the gene map Simon Wain-Hobson had brought to Bethesda. The Gallo map had a third gene, called "sor," that matched the gene the French called Q. It also contained a fifth gene, "3'orf," but the Gallo group hedged the question of whether the fifth gene really existed or was just an error in translation.

The major difference between Gallo's map and the one drawn by the French was in the fourth gene. If the leukemia virus was any guide, the fourth gene was probably the env, or envelope gene. But it was so much longer than the env gene in the leukemia virus that the Gallo group thought it had to contain the code for some other protein as well. But what function would such a protein be likely to perform?

The leukemia virus had a transactivator gene that appeared to switch the virus on after years, or even decades, of latency. Because the AIDS virus can also remain latent for long periods, the Gallo group thought the second half of the envelope gene was probably the AIDS virus transactivator. Because they weren't sure what it did, they called it "lor," for "long open reading frame." All together, Gallo's fourth gene was "env-lor."

According to Simon Wain-Hobson, Nature had originally expressed interest in publishing the French sequence paper, and when it was finished he gave them a call. "I said, you'll have our paper tomorrow," he said. "And then they didn't want it." Fortunately for the French, a journal called Cell, published by the Massachusetts Institute of Technology, was more receptive.

"They were naturally somewhat upset about this," recalled Benjamin Lewin, the editor of Cell. "They felt they had been working pretty much evenly with Gallo's group and suddenly they were not going to get their paper published maybe until months afterwards. We said, yes, we thought the sequence of the first isolate of the AIDS virus was a significant event. It didn't take us very long to decide that we should publish the paper and that we should publish it

As the cooks squabbled, the alphabet soup boiled down to HIV

As with mountains and galaxies, the naming of new viruses is a scientific honor reserved for their discoverers. Nomenclature in virology dates back to the time, not so long ago, when scientists' names were attached to the viruses they discovered. That is no longer common, but for Robert Gallo the best name for the virus that causes AIDS was the one that ensured its place as the newest member of his family of human retroviruses.

"Any impartial scientist," Gallo wrote to his French counterpart, Luc Montagnier, "will adopt the name HTLV-III. In fact, almost everyone in the U.S. and most people in Europe have already done so."

The French, understandably, preferred the name they had given their own isolate: LAV, which was short for lymphadenopathy-associated virus. Many other researchers, wishing not to anger Gallo but hoping to accord the French due credit as the discoverers, resorted to calling the virus HTLV-3/LAV. But each isolate of the AIDS virus was also given its own designation, and as more viruses were isolated the confusion engendered by such compound names was vastly increased.

The question was further complicated by the fact that the University of California's Jay Levy had found the AIDS virus independently—Levy said he had actually isolated the virus ahead of Gallo, but Gallo had published first—and Levy was calling his virus ARV, for AIDS-related virus.

"LAV is clearly an inaccurate name, and AIDS virus or AIDS related virus is the dumbest name I have heard yet," Gallo wrote to one colleague. "Clearly, human T-lymphotropic virus III is as accurate, as innocuous, and as consistent with the past as any name possible."

When Gallo was pressed for the rationale behind the name HTLV-3, he referred to a meeting at Cold Spring Harbor Laboratory on Long Island in September of 1983, where he had persuaded eight other scientists at a lobster dinner on the beach to join him in signing an "international agreement" that the next new virus related to his original human leukemia virus should be called HTLV-3.

The agreement, said British virologist Robin Weiss, who was among the signatories, had nothing to do with AIDS. It was was intended, he said, to resolve the dispute between Gallo and the Japanese over whether the leukemia virus should be called HTLV-1 or ATLV, the name being used in Japan.

Montagnier was there but wasn't asked to sign, Gallo said later, because "he only had one paper in the literature." In fact, Montagnier wouldn't have signed. "We never used the initials of HTLV," Montagnier wrote to Gallo later. "The initials of HTLV have been coined by you. In renaming this virus HTLV you have induced a lot of confusion amongst unaware people."

Gallo said his choice of names had been mandated by the "Cold Spring Harbor agreement." But in March of 1984 he wrote a personal letter to the editor of a London medical journal saying he was "debating whether to call [the AIDS virus] HTLV-III or HTLV-A (A = AIDS)."

Gallo chastised the French for having taken issue with his choice, imploring Montagnier to "save our energy in trying to contain the virus and the disease rather than to beat a dead horse over nomenclature." But it was Gallo who was firing off angry letters to colleagues whenever the name LAV appeared in a scientific paper. To one longtime collaborator who had used the French designation, Gallo wrote, "I cannot accept the excuse that: [a] 'you did not know,' or [b] 'the journal changed the name.'"

After nearly a year of dispute, the International Committee on the Taxonomy of Viruses stepped in. Under the chairmanship of Harold Varmus, the University of California virologist who won a Nobel prize last month, the committee assembled a panel to choose a new name. The panel included nearly everybody—Gallo and his friends, Robin Weiss, the French and the California ARV researchers—and the consensus was that none of the existing names was really right.

LAV wouldn't do, because it was possible to get AIDS without ever having had lymphadenopathy. ARV wouldn't do, because not everyone who was infected with the virus got AIDS. HTLV-3 was clearly wrong, because the AIDS virus had so little in common with the other HTLVs. The best name the group could come up with was human immunodeficiency virus, or HIV, a choice that Varmus concedes was less than inspired.

But when the 13-member panel published its decision in a letter to Nature, the letter bore only 11 signatures. Gallo and his closest colleague among the panelists, Max Essex of Harvard, had refused to sign.

Gallo vowed later never to use the new name. "The names of the virus that are already in the literature will be maintained," he said at the time. Although his AIDS papers referred to HTLV-3 for more than a year afterward, he has since joined the rest of the scientific community in adopting HIV.

JAN. 30, 1984: Using blood samples sent to Paris by the CDC, the Pasteur group finds antibodies to LAV in 10 of 10 patients with pre-AIDS and 3 of 10 with AIDS.

FEB. 7, 1984: In the keynote address at an AIDS symposium in Park City, Utah, **Gallo** says his "only candidate" for the AIDS virus is a close genetic variant of HTLV-1. His assistants passed a paper reporting that Claude Chandon

FEB. 9, 1984: **Gallo** writes **Jay Levy** that "HTLV itself . . . could still cause AIDS."

FEB. 13, 1984: **RF, SN, LS** and **BK** are still negative for electron microscopy. **Popovic** sends viruses called HTLVA and MO Variant to **Gonda** for observation.

FEB. 23, 1984: Lab notes show DNA being extracted from "LAV producer human cells." The French tell CDC they now have 11 retrovirus isolates from patients with AIDS and pre-AIDS.

FEB. 25, 1984: H9 and several other clones of the HT cell line are infected with the pooled virus culture **Popovic** now calls HT(pool

was infected with HTLV-1. **Jean-Claude Chermann** reveals that antibodies to LAV have now been found in 75 percent of pre-AIDS patients and 38 percent of those with AIDS.

FEB. 8, 1984: Pasteur researchers infect a new permanent cell line called FR8 cell line with LAV.

Robert Gallo (left) and Luc Montagnier

FEB. 14, 1984: Chermann, attending an NCI seminar, asks Popovic if he has succeeded in growing the LAV sent from Paris. "I cannot speak," **Popovic** replies. "Only the boss can speak."

FEB. 22, 1984: **Gonda** reports observing lentivirus in "HTLVA" and "MO Variant."

FEB. 27, 1984: CDC sends blood samples to **Gallo** and the French for testing with their respective AIDS tests. Same day, Pasteur researchers infect a new cell line called BJAB with LAV.

Nobel elicits ignoble ambition

Claim to have discovered HIV undid researcher Robert Gallo

Science Fictions
The War Between the Scientists Who Discovered HIV
By John Crewdson
Little Brown and Co., 688 pages, $39.95

MARK WAINBERG
Special to The Gazette

Studies have shown that peer approval and recognition are the most important factors that motivate scientists to achieve greatness. Many non-scientists might have difficulty identifying with this notion. After all, in the world of business and sports it is seemingly ever-higher salaries and other monetary considerations that drive people to do their best. But for scientists, ultimate recognition is really the Nobel Prize, sought by many and received by few. Among those who either covet a Nobel or who believe that they have a realistic chance of winning one, the quest can become all-consuming.

In this book, John Crewdson, a Pulitzer Prize-winning journalist at the Chicago Tribune, has chronicled the manner in which the need to be identified as the discoverer of HIV, the virus that causes AIDS, caused the well-known virologist Robert Gallo to embark on a course that would prove destructive for Gallo himself as well as for many of his colleagues, including a rival group of scientists at the Pasteur Institute in Paris, headed by professor Luc Montagnier.

The book is a detailed expansion of a riveting series of articles that Crewdson wrote on this subject for the Chicago Tribune in 1996. It includes a wealth of details that were omitted from the original, shorter version, and this is both its strength and its weakness. Notably, while the case that Crewdson, writing almost as a prosecutor, builds against Gallo is compelling, it is so detailed as to risk boring the casual reader.

It is hard to know what might have motivated Crewdson to write this lengthy description of the events surrounding the discovery of HIV. It is clear, however, that he must have felt a need to portray the excesses of human behaviour that can emerge when participants feel that a Nobel Prize is on the line, and that Gallo's excesses in pursuit of this goal were so egregious as to warrant full documentation.

Indeed, the author comes across as an excellent prosecutor. Readers who are fans of courtroom dramas or novels will know that such individuals are determined to obtain a conviction, even if it sometimes means providing an interpretation of events that best fits the prosecutorial thesis. This is clearly the case here thought it is doubtless within the scope of journalistic license.

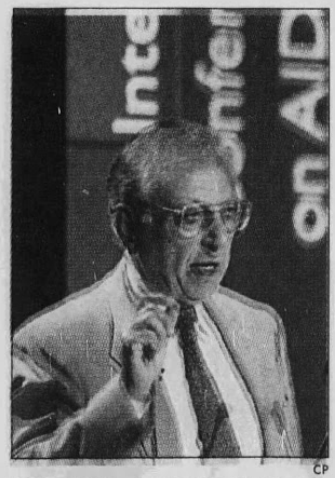
FACTUAL ERRORS

There are, however, several factual errors in this version of events. First, in the introductory pages, Crewdson makes the point that Gallo was extremely stingy and did not make his reagents and resources available to other laboratories for their own research. This is largely untrue. Indeed, the reviewer of this book received HIV from Gallo's lab in 1984, shortly after publication of Gallo's papers in Science (notwithstanding the fact that Gallo had appropriated the virus from the French) as well as cells in which to replicate the virus and monoclonal antibodies with which to perform biochemical analysis.

Gallo also made these reagents available to scientists from many laboratories around the world. Sadly, however, he refused to provide these same materials to many others, whom he might have perceived as enemies or competitors, and in this context Crewdson is dead-on.

Another example of a misstep by Crewdson is his statement that the first human retrovirus to be isolated, HTLV-I, a cause of a rare form of leukemia, was first identified by Frank Ruscetti and Bernard Poiesz at the National Cancer Institute in Bethesda, Md. Although this statement is true, Crewdson ascribes no credit to Gallo for this discovery. Yet both Ruscetti and Poiesz were postdoctoral fellows in Gallo's laboratory at the time that this work was done. Crewdson surely knows that it is accepted procedure for the head of a laboratory to claim credit for research conducted on his premises by more junior scientists.

It is sad that these shortcomings detract from what is otherwise a compelling case that Gallo claimed and obtained recognition for research that had, in fact, been accomplished by the French. But what Crewdson fails to acknowledge is that the work conducted in Gallo's laboratory added new findings to those that had been published by the French and that the cumulative effect of the research efforts of both groups was to spur the field forward much faster than would otherwise have been the case.



CP

Robert Gallo speaks at a Vancouver AIDS conference in 1996.

LACK OF OBJECTIVITY

It is probably incorrect to state, as Crewdson does, that the in-fighting between the American and French groups slowed the development of a blood test that could safeguard the blood supply against HIV-1 contamination. In reality, both groups contributed to the development of such tests.

Further evidence of the author's lack of objectivity is the inference that Gallo may have personally unplugged freezers that contained stockpiles of viruses that he was anxious to destroy, so that other scientists could neither corroborate nor contest the validity of his results. And, in fairness, the implication that Gallo deliberately stole the French virus is impossible to prove. It remains entirely possible that sloppy research led to the contamination of cultures in Gallo's laboratory by the French HIV isolate that grew out and was later claimed by the Gallo laboratory to be their own.

Although this book describes the history of the first cases of HIV/AIDS in the United States in succinct fashion, it misses out on one of the most important aspects of the epidemic – the extent of human suffering that has been wrought by HIV throughout the world. The book makes little mention of the important issues of drug access, attempts to develop a vaccine against HIV-1 and the ability of the virus to mutate with amazing agility, giving rise to problems of drug resistance as well a wide array of HIV strains that differ from one another with regard to immunological makeup.

Simply put, this means that it may be impossible to design a single vaccine that will protect against all forms of HIV-1. The latter issue is so important that it ensures that HIV will continue to be one of the world's most important problems in public health for many years to come.

Although the roles of the French vs. U.S. scientists in regard to the research performed are well described, it is also probably unfair, in spite of his undeniable faults, to single out Gallo as the sole villain of the piece. Most scientists in the field concur that the leader of the French group, Luc Montagnier, was himself prone to fits of vanity in regard to his own role in the story.

The book also gets sidetracked by the personal lives of some of its leading characters, and Crewdson seems to take joy in describing the extramarital relationships of some of them. In reality, these tidbits of information only detract from the main theme – how the quest for scientific glory, if taken to excess, can do harm.

In summary, this book is a successful indictment of Gallo, whom history will probably judge to have been guilty of excessive zeal in the pursuit of scientific glory. However, there are certainly worse crimes and the fact remains that the research performed in the Gallo lab helped advance HIV drug discovery and the development of antiviral treatments that have enabled many hundreds of thousands of people around the world to live longer and enjoy higher quality lives.

Most scientists, even those who have large laboratories, are not prone to the types of excessive behaviour attributed to Gallo in this book. At the same time, most scientists would be happy to leave behind his long and distinguished legacy of scientific accomplishment.

✤ *Mark Wainberg is director of the McGill University AIDS Centre at Montreal's Jewish General Hospital and past president of the International AIDS Society. He is acquainted with almost all the scientists described in this book.*

1972 (June 25) - NYTimes : "Litton to Run Cancer Research Lab"

By Harold M. Schmeck Jr.; Special to The New York Times

Source : [HN012A][GDrive]

WASHINGTON, June 24— The National Cancer Institute named a contractor yesterday to operate its newly acquired facilities at Fort Detrick, Md., and predicted that, by fall, the former biological warfare lab oratories would be fully at work toward the conquest of cancer.

The contract, for renovation, management and operation of the facilities, goes to Litton Bionetics, a division of Litton Industries, Inc. The first - year contract is for $6.8 - million. At a news conference today, Dr. Frank J. Rauscher Jr., director of the cancer institute, said it was the largest single contract ever awarded by any of the National Institutes of Health.

Use of the facilities is part of the expanded national re search effort against cancer Fort Detrick is believed to have some of the world's best facili ties for research with hazardous chemicals and infectious agants.

Dr. Rauscher said the insti tute's work at Fort Detrick would include research on known cancer viruses of ani mals as well as some of the viruses suspected of roles in human cancer. The program will also include studies of chemicals capable of causing cancer and research on poten tial anticancer drugs.

Viruses to Be Made

Viruses and special biologi cal materials will be produced in large quantities for use, not only at Fort Detrick, but also at other laboratories doing cancer research.

Large numbers of small ani mals, mostly rats and mice, will be maintained for the re search at the newly acquired laboratories in Maryland. By the end of the second year of op eration, 30,000 laboratory ani mals will be maintained at the facilities for studies of the life time effects of hazardous chem icals and other potentially dangerous substances. Presum ably, this will be only part of the animal population.

Dr. Rauscher said the agree ment with Litton Bionetics of Bethesda, Md., was an award fee contract, meaning that the contractor has no guaranteed, profit. Only if the Government finds that the company's pro gress warrants it, will the con tractor be premitted some percenage or profit up to a possi ble maximum of 10 per cent, he said.

The over - all operational con tract is expected to expand in future years, perhaps reaching a legal level as high as $20 - million a year.

Fast Action Planned

At the news conference to day James C. Nance, president of Litton Bionetics, said the company planned to go into operation rapidly with an esti mated 75 persons on duty by the end of next week; 150 by the end of July and approach ing 300 by 1973.

Bionetics, which became a division of Litton Industries in 1968, has been active as a commercial biological research laboratory since 1961 and has done a substantial amount of previous contract work for the cancer institute. Litton Indus tries has come under sharp criticism recently for its per formance in ship - building con tracts for the Navy.

While Fort Detrick has been a largely secret facility while it was working on biological war fare research, it will now be open to scientists from the United States and abroad, in cluding some from the Soviet Union and, probably, from mainland China.

Dr. Rauscher said that some virus experts from the Soviet Union might be invited to tour the Fort Detrick facilities as early as this fall.

The cancer institute's opera tion at Fort Detrick will be located primarily in the “high security area” of the former biological warfare research fa cility.

1985 (Sep 2) - Washington Post : "Hazleton Labs Buys Litton Bionetics Units"

By Nell Henderson

Source : [HN012B][GDrive]

Hazleton Laboratories Corp. has acquired the animal and molecular toxicology units of Litton Bionetics from Litton Industries Inc. for an undisclosed amount.

Hazleton, based in Vienna, provides biological and chemical research services, manufactures laboratory and medical products, and is a major supplier of research animals. Litton Bionetics, based in Kensington, provides biomedical research and testing services and sells diagnostic products.

Litton Industries said recently that it had agreed to sell 50 percent of its Bionetics subsidiary to a Dutch company, Akzo N.V., and 25 percent to MetPath Inc., a subsidiary of Corning Glass Works. Hazleton said last week that it has agreed to buy the remaining 25 percent by leasing the facilities and paying cash for the assets, with the sale to be completed by Sept. 1.

Bionetics's toxicology units conduct tests of new substances for manufacturers that plan to use them in food, pharmaceuticals and cosmetics. The Food and Drug Administration requires such substances undergo tests to determine whether they have toxic effects, cause cancer or genetic mutations or have other dangerous properties. Both Litton Bionetics and Hazleton test effects of substances on laboratory animals.

The toxicology units employ about 200 workers and together generate annual sales of about $10 million.

Hazleton recently reported earnings of $2.2. million on sales of $55.9 million for its fiscal year, ended June 30.

2001 - Suppressed inventions

AIDS and Ebola: Where Did They Really Come Prom?

Dr. Leonard G. Horowitz

During the 1960s and early 1970s the World Health Organization functioned as the omnipotent supplier and standardizing authority of the world's experimental pharmaceuticals. In the field of virology, the United States Public Health Service (USPHS) and National Institutes of Health (NIH) directed the National Cancer Institute (NCI) to become, along with the Centers for Disease Control and Prevention (CDC) the WHO's chief distributor of viruses and antiviral vaccines. The WHO Chronicle noted by 1968—ten years into the WHO's viral research program—"WHO virus reference centres" had served as authorized technical advisors and suppliers of "prototype virus strains, diagnostic and reference reagents (e.g., antibodies), antigens, and cell cultures" for more than "120 laboratories in 35 different countries." Within a year of this announcement, this number increased to "592 virus laboratories . . . [and] only 137 were outside Europe and North America." Over these 12 months, the NCI and CDC helped the WHO distribute 2,514 strains of viruses, 1,888 ampoules of antisera mainly for reference purposes, 1,274 ampoules of antigens, and about 100 samples of cell cultures. More than 70,000 individual reports of virus isolations or related serological tests had been transmitted through the WHO-NCI network. 1 '2

At the NCI in Bethesda, Maryland, from the late 1960s to the present, the chief retrovirus research laboratory was associated with the Department of Cell Tumor Biology, and chaired by Dr. Robert Gallo—an esteemed member of the National Academy of Sciences (NAS) who was hailed by the U.S. Secretary of Health and Human Services Margaret Heckler in 1984 as the discoverer of the AIDS virus, HTLV-m. LAV, identical to HTLV-m had been isolated by Montagnier's French team and allegedly forwarded to Gallo in 1983.3

MILITARY ORDERS FOR AIDS-LIKE VIRUSES: THE BIOLOGICAL WEAPONS CONTRACTORS

As early as 1970, the U.S. Department of Defense (DOD) appropriated at least $10 million to "initiate an adequate program through the National Academy of Sciences-National Research Council (NAS-NRC)" to make a new infective microorganism which could differ in certain important aspects from any known disease-causing organisms. Most important of these [aspects] is that it might be refractory to the immunological and therapeutic processes upon which we depend to maintain our relative freedom from infectious disease. Members of the NAS-NRC had instructed scientific leaders in the DOD this work might be accomplished "within 5 years."4 This research was then carried out by American defense contractors despite the authorization and signing of the Geneva accord by Dr. Henry Kissinger and President Nixon outlawing the production and testing of such biological weapons.5

Also in 1970 Gallo and his co-workers presented research describing the experimental entry of bacterial ribonucleic acid (RNA) into human white blood cells (WBCs) before a special symposium sponsored by NATO.6 The paper published in the Proceedings of the National Academy of Sciences discussed several possible mechanisms prompting the "entry of foreign nucleic acids" into lymphocytes—the cells principally attacked by HTV. Prior to this, Gallo et al. had published studies identifying:

1. mechanisms responsible for reduced amino acid and protein synthesis by T-lymphocytes required for immunosuppression;7

2. specific enzymes required to produce such effects along with a “base pair switch mutation” in the genes of WBCs to create immune system dysfunction;8 and

3. methods by which WBC “DNA degradation” and immune system decay may be prompted by the “pooling” of purine bases and/or the addition of specific reagents.9

Subsequent studies published in 1970 by Gallo and co-workers identified “RNA dependent DNA polymerase” (i.e., the unique AIDS-linked enzyme, reverse transcriptase) responsible for “gene amplification ... biochemical cytodifferentiation,” (i.e., the development of unique WBC characteristics including cancer cell production) and “leukaemogenesis”; 10 and identified L-Asparaginase synthetase—a key enzyme that, if repressed, will induce treatment resistant leukemias and other cancers. 11

The year following the $10 million appropriation by the DOD for AIDS-like biological weapons research, the NCI acquired the lion's share of the facilities at

America's premier biological weapons testing center, Fort Detrick in Frederick, Maryland. 12 Perhaps not coincidentally, the Cell Tumor Biology Laboratory's output increased in 1971 as measured by the publication of eight scientific articles by Gallo and co-workers compared to at most four in previous years. These reports included Gallo's discovery that by adding a synthetic RNA and feline (i.e., cat) leukemia virus (FELV) "template" to "human type C" viruses (associated with cancers of the lymph nodes), the rate of DNA production (and subsequent provirus synthesis) increased as much as thirty times. The NCI researchers reported that such a virus may cause many cancers besides leukemias and lymphomas including sarcomas. 13

In this 1971 report Gallo et al. also reported modifying simian (i.e., monkey) viruses by infusing them with cat leukemia RNA to make them cause cancers as seen in AIDS patients. 13

Furthermore, Fujioka and Gallo concluded from studies conducted in late 1969 or early 1970 that they would need to further "evaluate the functional significance of tRNA changes in tumor cells," by designing an experiment in which "specific tumor cell tRNAs" would be "added directly to normal cells." They explained that one way of doing this was to use viruses to deliver the foreign cancer producing tRNA to normal cells. The viruses which were then employed to do this, the researchers noted, were the simian virus (SV40) and the mouse parotid tumor (polyoma) virus. 14

Such experiments clearly advanced immunodeficiency virus technology and even provided a model for the development of HTV, the AIDS virus—allegedly of simian virus descent—which similarly delivered unique enzymes and a foreign RNA to normal cells necessary to cause an acquired immunodeficiency syndrome in animals and humans.

DEVELOPING MORE AIDS-LIKE VIRUSES

In 1972, Gallo, his superiors and inferiors studied portions of simian viruses to determine differences in RNA activity between infected versus uninfected cancer cells, and whether the differences could be ascribed to the infection and related DNA alterations. 15 They stated that "by studying viral or cellular mutants or cell segregants . . . which have conditional variations in virus-specific cellular alterations, it should be possible to more precisely determine the biological significance of the RNA variation reported here."

Clearly, the group was working to determine the relevance of various viral genes on the development of human cancers and immune system collapse. They reported their desire to use this information to find a cure for cancer, but at this time their activity was more focused on creating various cancers as well as new carcinogenic viruses which could infect humans.

For example, Smith and Gallo published another National Academy of Sciences paper examining DNA polymerase (i.e., reverse transcriptase) activity in immature normal versus acute leukemic lymph cells. To do so, they evaluated the single stranded 70S RNA retrovirus found in chickens which causes prominent features of AIDS including WBC dysfunction, sarcomas, progressive wasting and death. 16 Borrow, Smith and Gallo injected this chicken virus RNA into human WBCs to determine if the cells were prompted to produce proteins (including new viruses) encoded by the viral RNA.17 Robert, Smith and Gallo also evaluated the neoplastic effects of single stranded 70S RNA reverse transcriptase delivered by the cat leukemia virus (FELV) and the mason-Pfizer monkey virus on normal human lymphocytes (NHL). 18

This work foreshadowed the observation made ten years later by the CDC's chiefAIDS researcher, Dr. Donald Francis who noted the "laundry - list" of feline leukemia-like diseases associated with AIDS.3

Other examples are detailed by Gallo and co-workers while discussing their adapting monkey, rat, and bird leukemia and tumor viruses fQr experimental use in a human (NG-37) cell line. 19 Wu, Ting and Gallo20 discussed the synthesis of new RNA tumor viruses "induced by 5-iodo-2'-deoxyuridine, IdU (a constituent of RNA) in rodent cell cultures, and noted that chemotherapy might be used to halt the reverse transcriptase-linked viral reproduction.

Howeyer, had HTV been synthesized for military purposes from various species components, it would be difficult, if not impossible, to prove. As Gillespie, Gillespie and Gallo et al. noted in 1973 concerning the origin of the RD114—another cat/human bioengineered virus—"it can always be argued that" a virus which naturally jumped species (as HIV is alleged to have done from the monkey) would be expected to have antigens that differ "from the antigen found on the viruses of known" origin.21

LITTON BIOHETICS: GALLO 'S LINK TO THE DOD

Four years later, during a U.S. Senate investigation of illegal "biological testing involving human subjects by the Department of Defense," Senators learned that Bionetics, Bionetics Research Laboratories, and Litton Bionetics—an organization which, along with the NCI, administered

and provided Dr. Gallo's research funding (10, 13, 15, 17-19, 22, 26) were not only acknowledged DOD biological weapons contractors, but their affiliated Litton Systems, Inc., was among the most frequently contracted institutions involved in biological weapons research and development between 1960 and 1970 (the end of the reported period).23 Additional biological weapons contractors with whom Dr. Gallo and/or his co-workers associated during the late 1960s and early 1970s included the University of Chicago,24 Texas,13 Virginia,25 and Yale,17 Merck and Co. Inc., 20 and Hazelton Laboratory, site of the famous 1989 Marburg-Ebola-like (Reston) virus outbreak.22

NCI staff reports revealed that Litton Bionetics had been granted the service contract to supply all NCI researchers, worldwide, with virtually every primate cancer research material requested, including seed viruses, viral hybrids, cell lines, experimental reagents, and African colony born monkeys including M. mulatta and C. aethiops which were associated with the major monkey AIDS virus outbreaks in California's Davis Lab, and the 1967 Marburg virus outbreaks in three European vaccine production facilities. 15"17

Litton Bionetics chief John Landon reported an experiment begun in 1965 when he inoculated 18 monkeys with rhaabdovirus simian—a rabies virus known to cause Ebola-like hemmorhagic fever in monkeys. "Nine [monkeys] died or were transferred," to allied laboratories or vaccine production facilities. This shipment was likely to have started the first hemmorhagic fever "Marburg virus" outbreak among European vaccine laboratory workers in 1967. As noted by the world's leading simian virus expert at the time, Dr. Seymour Kalter, the Marburg virus was apparently manmade.23-25

In fact, Litton Bionetics, the chief military and industrial supplier of primates for cancer virus experimentation during the 1960s and early 1970s, also maintained the colony of the specific genus of monkeys associated with all of the major monkey ADDS virus outbreaks in the United States.23

Through telephone interviews with Litton Bionetics and MedPath administrators, I learned that Bionetics Research Laboratories had been sold to MedPath Corporation—one of America's largest medical and blood testing laboratories—a division of Dow Corning. Dow Coming's parent, Dow Chemical Company, was alsp listed among the Army's chief biological weapons contractors during the 1960s and early 1970s.2627 Litton Bionetics, a subsidiary of Litton Industries, Inc. remains in business as a proprietor of the Frederick Cancer Research Center, a "privately owned, government contracted" facility. Bionetics, it was noted, currently acts as an agency under "contract to manage and operate the Frederick (Md.) [Fort Detrick affiliated] Cancer Research Center for

the National Cancer Institute." 27 Besides administering research grants and government funds earmarked for the NCI, Litton Bionetics also developed a division which produced and marketed test kits for bloodborne, infectious diseases including mononucleosis, hepatitis B, and AIDS.28 This division was sold to Organon Teknica in 1985.26

Apparently, the military-medical-industrial complex was well aware of Litton Industries' service as a DOD and NATO contractor. In 1978, the company was indicted for filing false claims for $37 million in cost-overruns during the building of three nuclear submarines under one of several multi-billion dollar defense contracts.29"34

ZAIRE AND ANGOLA: A CIA MILITARY ARENA

Between 1970 and 1975, the period the NAS-NCR scientific advisors informed DOD decision-makers that AIDS-like viruses could be readied,4 American cold war efforts focused on Zaire and Angola.33"35 Following the withdrawal of American forces in Vietnam, Secretary of State Henry Kissinger ordered the CIA to begin a major covert military operation against MPLA (communist bloc backed) "rebels" in Angola.36,37 Zaire, indebted by over $4.5j billion to the International Monetary Fund, and headed by President Mobutu—paradoxically regarded as one of the world's wealthiest men with "a personal fortune put at $2,939,200,000 [1$84 estimate] banked in Switzerland—was wooed by NATO allies during the 1970s (principally the U.S.) to be a staging area for CIA backed, Portuguese, French, and mainly South African mercenaries.38'39 "American corporate investment, notably in copper and aluminum, doubled to about $50 million following a 1970 visit by Mobutu to the United States. Major investors included Chase-Manhattan, Ford, General Motors, • Gulf, Shell, Union Carbide, and several other large concerns."43

However, in 1975 Mobutu apparently turned against NATO allies and increased negotiations with China and Russia40,41 He proclaimed his intention to nationalize foreign owned enterprises 42,43 In June 1975, following the CIA's thwarted efforts to convince the U.S. Congress to appropriate more funds for Mobutu and the Angola programme (A total of $3 1 .7 million had already been "drawn from the CIA's FY 75 contingency fund" which was "exhausted on 27 November 1975").39 Mobutu expelled the American ambassador and arrested many of the CIA's Zairian agents, placing some under death sentences.40,41

The following year, in October 1976, the "Ebola Zaire virus" broke-out in "fifty five villages surrounding the [Yambuku] hospital" first killing "people who had received injections." Mobutu then ordered his army to "seal off the Bumba zone with roadblocks" and "shoot anyone trying to come out" so "no one knew what was happening, who was dying, [or] what the vilrus was doing."44

Shortly thereafter, Ebola victim specimens were sent to the CDC, Special (meaning "secret" within the American intelligence community) Pathogens Branch; to Porton, England's controversial chemical and biological weapons (CBW) laboratories;45 and teams of WHO and CDC researchers were dispatched to the Ebola region in Mobutu's private, American supplied C-130 Buffalo troop-transport plane.44

By the end of 1976, the Zairian leader had reconciled his differences with the American intelligence and corporate communities believing that Zaire would continue to reap his non-communist allies' social and economic aid. On April 4, 1977, Mobutu suspended diplomatic relations with Cuba; on April 21, reduced ties with the Soviet Union; and on May 2, he cut ties with East Germany.46 Meanwhile, according to John Stockwell, Former Chief of the CIA's Angola Task Force, "the United States was exposed, dishonored and discredited in the eyes of the world," as "15,000 Cubans were installed in Angola"40 despite the CIA's best efforts and a continuing policy of lying "to State Department officials, Congressmen, American press, and world public opinion in varying degrees, depending on the need" about the CIA's covert military campaign in Angola and Zaire.39

Throughout 1976 and 1977, Mobutu, NATO, and the CIA, constrained by the Tunney, Cranston and Clark amendment which prevented the expenditure of American funds in Zaire/Angola, except to gather intelligence, 39 remained embroiled in the "Shaba rebellion" against allegedly Russian-backed "Katangan rebels."46

At the same time, perhaps not coincidentally, NATO ally West Germany was pouring financial aid into Zaire and white ruled South Africa.47-49 The Northeast region of Zaire, believed to be the epicenter of the AIDS epidemic, was specifically targetted for West German economic aid and industrialization.50

The "long tradition of friendship between Germans and South Africans" London's African Development noted, "dates back from the first waves of white immigrants to South Africa and the feeling of solidarity between Germans and Afrikaners during the Boer War, continuing throughout the First World War and then the Second World War. Many of today's Nationalist leaders in Pretoria," the paper reported, "were Nazi sympathizers: many ex-Nazis settled in South Africa after 1945 . . ,"48

THE WEST GERMAN COMPANY OTRAG

Not surprising then, on March 26, 1976 Mobutu signed what the British Broadcasting Company (BBC) reported was a "secret agreement" with the West German company OTRAG (Orbital Transport-und Raketen-Aktiengesellschaft) to lease 260,000 square kilometers—essentially the complete Kivu province—for military/industrial purposes for the sum of DM 800,000,000 (approximately $250 million at that time).51"54 The contract "made OTRAG sovereign over territories once inhabited by 760,000 people"54 in the Eastern and South-central portion of Zaire. The leased property positioned North of the Shaba militarized region, expanded Southeast along the Congo River—the countries main waterway, and south of the Kinshasa highway—better known as the "AIDS Highway" which runs through Zaire's Northeast corridor and across central Africa bypassing the "Isle of Plaques," Mount Elgon and Kitum Cave allegedly by the author of The Hot Zone to be the breeding ground for the Ebola, Marburg, and AIDS viruses.44

OTRAG was apparently authorized to conduct any "excavation and construction; including air fields, energy plants, communication systems, and manufacturing plants. All movement of people into and within the OTRAG territory was only with permission of OTRAG, [which was] absolved from any responsibility for damage caused by construction. Its people enjoy complete immunity from the laws of Zaire in the granted territory, until the year 2000."56

Believed to be of military intelligence gathering significance to NATO46"48 ' 55> 56 OTRAG and its principals were traced back to the West German government and "to those Nazi scientists who worked on VI and V2 rockets during World War n. For example, Dr. Kurt H. Debus, Chairman of the Board of OTRAG, once worked at the Peenemude V2 program and later, until 1975, worked as director of the Cape Canaveral (now Cape Kennedy) space program. Richard Gompertz, OTRAG's technical director and a U.S. citizen, once was a specialist on V2 engines and later presided over NASA's Chrysler space division. Lutz Thilo Kayer, OTRAG's founder and manager, when young was quite close to the Nazi rocket industry, often called 'Dadieu's young man,' a reference to Armin Dadieu, his mentor, whaserved as prominent SS officer and as Gorling's special representative for a research program on storing uranium. While working for OTRAG Kayser also acted as a contact for the West German government, a special advisor to the Minister of Research and Technology on matters concerning OTRAG. He was also on the ad hoc committee on . . . [America's] Apollo program."56

In 1979, under pressure from the Soviet Union and Zaire's neighboring countries, Mobutu announced OTRAG would "halt its rocket testing" program. It was clear, however, strong diplomatic, military, and economic ties between West Germany, the U.S. and Zaire continued.48,57

clear, however, strong diplomatic, military, and economic ties between West Germany, the U.S. and Zaire continued 49,57

COLD WAR PROPAGANDA VERSUS THE HARD CORE PACTS

According to the latest United States Army (USA) report, the "outlandish claim" that the AIDS virus was developed as a biological weapon for the Pentagon was communist propaganda "disavowed in 1987 by then Soviet President Mikhail Gorbachev, who apologized to President Ronald Reagan for the accusation."58 However, more recently, the high ranking Soviet press official Boris Belitskiy, offered an alternative account regarding the origin of such "propaganda."59

"Several U.S. Administration officials such as USIA [CIA] Director Charles Wick, have accused the Soviet Union of having invented this theory for propaganda purposes. But actually, it is not Soviet scientists at all who first came up with this theory," Belitskiy reported. "It was first reported in Western journals by Western scientists, such as Dr. John Seale, a specialist on venereal diseases at two big London hospitals.

"Just recently a Soviet journalist in Algeria, Aleksandr Zhukov, managed to interview a European physician at the Moustapha Hospital there, who made some relevant disclosures on the subject. In the early seventies, this physician, an immunologist, was working for the West German OTRAG Corporation in Zaire. His laboratory had been given the assignment to cultivate viruses ordinarily affecting animals but constituting a potential danger to man. They were particularly interested in certain unknown viruses isolated from the African green monkey, and capable of such rapid replication that they could completely destabilize the immune system. These viruses, however, were quite harmless for human beings and the lab's assignment was to develop a mutant virus that would be a human killer." 711 ' 13 22

"Did they succeed?" the announcer asked. 'To a large extent, yes," Belitskiy replied. "The lab was ordered to wind up the project and turn the results over to certain U.S. researchers, who had been following this work with keen interest, to such an extent that some of the researchers believed they were in reality working not for the West German OTRAG Corporation but for the Pentagon."59

Two years after Belitskiy's announcement, in 1991, Dr. Jacobo Segal, professor emeritus of Berlin's Humboldt University told the international press that the Pentagon theory of AIDS made sense. He alleged the virus was likely developed "through gene technology" as a result of Pentagon sponsored animal research, "to permit the attack on human immune cells." Furthermore, he reported this theory is "supported by many European scientists and has not been refuted."60

In 1977, at the height of OTRAG's Zairian missile testing phase, Litton Industries units received contracts worth: $5 million for medical electronic equipment from its Hellige division, in Freiburg, West Germany;61 $19.8 million worth of missile fire-control equipment from the Army;62 $32.9 million for electronic reconnaissance sensor equipment from the Air Force;63 and in 1978 $11.3 million worth of computerized communications systems for NATO.64 Some of these military supplies may have been earmarked for OTRAG.65

Moreover, given the "cooperation between NATO and the World Health Organization with regard to the control and regulation of the international exchange of pharmaceutical products, [and] the possible necessity of facing the dangers created by the use of chemickl or bacteriological weapons"66 It appears noteworthy that the outbreaks of the world's most feared and deadly viruses Marburg, Ebola, Reston, and AIDS—share the dubious distinction of breaking out in or around zones of U.S. and West German, NATO-allied, military experimentation at the height of the cold war; increased political/military interest in Central Africa, and a burgeoning of WHO and NCI contracts for the supply of simians for "defensive" research.44

AIDS, GAYS, BLACKS AHD THE CIA

It is also noteworthy that in 1975, five years following the signing of the Geneva accord by Nixon, congressional records revealed that the USPHS through the Special (i.e., covert) Operations Division of the Army continued to supply biological weapons including deadly neurotoxins and viruses to the CIA which illegally stored them in their Fort Detrick facility for future unsanctioned uses 67 Though records of who initiated and directed this covert activity were destroyed by the CIA, along with the famous Watergate tapes,68 Mr. Nathan Gordon, Former Chief of the CIA's Chemistry Branch, Technical Services Division confessed knowledge that some of the stored substances were to be used to "study immunization methods for diseases vis-a-vis—who knows, cancer."69 . Furthermore, following Nixon's resignation, President Ford and Henry Kissinger were made aware that the CIA maintained a residual supply of biological weapons, but neither ordered their destruction according to testimony provided by Former CIA Director Richard Helms.70

In subsequent congressional hearings before the Senate Subcommittee on Health and Scientific Research, it was revealed that George W. Merck, "of the prominent Merck pharmaceutical firm," directed America's biological weapons manufacturing industry for decades following World War

II 71 Merck & Company, Inc. was also listed among the DOD biological weapons contractors.72 Merck, Sharp and Dohme provided major financial support for the earliest hepatitis B vaccination studies conducted simultaneously in Central Africa and New York City during the early 1970s. Several authorities have argued these vaccine trials might best explain the unique and varying epidemiological patterns of HIV/AIDS transmission between the U.S. and Africa. "The vaccine was prepared in the laboratories of the Department of Virus and Cell Biology Research, Merck Institute for Therapeutic Research, West Point, Pennsylvania. The placebo, [was] also prepared in the Merck Laboratories."72

During the holocaust, Nazi scientists assayed non-Arian blood to determine race specific disease susceptibilities. Blacks and homosexuals, along with Jews, were persecuted by the Nazis. Over 10,000 gay men were murdered. 3

Similarly, U.S. intelligence agencies have been targeting blacks and gays for assassinations, harassment, illegal wire taps, and counterintelligence campaigns from the McCarthy era in the 1950s through the Reagan era in the 1980s. American black and gay civil rights groups and their leaders were considered communist threats during the cold war years — particularly during the late 1960s and early 1970s when Nixon, Kissinger, and Hoover supported COINTELPRO funding for covert FBI and CIA activities aimed at neutralizing all such domestic and foreign black and homosexual threats. 74-78

The use of Third World people and American, blacks and prisoners for unconscionable pharmaceutical experimentation and covert economic, social, and environmental exploitation by the U.S. and other western countries has been repeatedly alleged by reputable sources.79

1991 (Jan 31) - Chicago Tribune : EX-GALLO AIDE CHARGED WITH EMBEZZLEMENT

Source : [HN010Z][GDrive]

John Crewdson, Chicago TribuneCHICAGO TRIBUNE

A former longtime deputy to AIDS researcher Dr. Robert Gallo has been charged with stealing $25,000 that a German pharmaceutical firm paid the U.S. government for biological research in the Gallo laboratory.

The former deputy, Dr. Prem Sarin, 57, was charged by a federal grand jury here last week with embezzlement and three other violations of federal law, including two felony charges of making false statements on financial disclosure forms.

Sarin is the second scientist from the Gallo lab to have been charged with criminal offenses by the U.S. attorney`s office here. Last year, Syed Salahuddin, another longtime Gallo aide, pleaded guilty to accepting illegal gratuities from a Maryland company that supplied the Gallo lab with services and materials.

Ties between that company, Pan-Data Systems, and another Gallo assistant, Dr. Dharam Ablashi, are being investigated by Richard Kusserow, inspector-general of the Department of Health and Human Services, according to sources familiar with that investigation.

Kusserow`s investigators are also conducting an inquiry into possible perjury and false statements by Gallo himself in connection with his prize-winning AIDS research at the National Cancer Institute in suburban Bethesda, Md., just outside Washington.

The cancer institute is part of the National Institutes of Health, which is an agency of the Department of Health and Human Services. Kusserow, who previously headed the white-collar fraud unit in the Chicago office of the Federal Bureau of Investigation, has oversight responsibility at HHS.

According to federal court files in the Sarin case, Sarin had tentatively agreed to plead guilty earlier this month to two lesser offenses. When that deal fell through, federal prosecutors asked the grand jury to charge the scientist with four violations of law, including embezzlement.

The offenses to which Sarin had agreed to plead guilty carry a maximum penalty of six years in prison and a $350,000 fine. The maximum for the four offenses with which he is now charged is 21 years in prison and a fine of $850,000.

Asked why his client had chosen to stand trial, Sarin`s attorney, W. Neil Eggleston, said only, "He`s innocent." Eggleston declined to confirm reports that Sarin had repaid the $25,000 that is the focus of the alleged embezzlement.

Other sources close to the case suggested that Sarin had withdrawn from the deal because of prosecutors` insistence that any plea bargain include some jail time.

Lieutenant, junior grade

Richard Green Lugar (April 4, 1932 – April 28, 2019) was an American politician who served as a United States Senator from Indiana from 1977 to 2013. He was a member of the Republican Party.

Born in Indianapolis, Lugar graduated from Denison University and the University of Oxford. He served on the Indianapolis Board of School Commissioners from 1964 to 1967 before he was elected to two terms as mayor of Indianapolis, serving from 1968 to 1976. During his tenure as mayor, Lugar served as the president of the National League of Cities in 1971 and gave the keynote address at the 1972 Republican National Convention.

In 1974, Lugar ran his first campaign for the U.S. Senate. In the year's senate elections he lost to incumbent Democratic senator Birch Bayh. He ran again in 1976, defeating Democratic incumbent Vance Hartke. Lugar was reelected in 1982, 1988, 1994, 2000, and 2006. In 2012, Lugar was defeated by Indiana State Treasurer Richard Mourdock in the Republican primary, ending his 36-year tenure in the U.S. Senate. Lugar ran for the Republican nomination for President of the United States in the 1996 primaries but lack of success led to his withdrawal early in the campaign.

During Lugar's tenure, he served as Chairman of the Senate Committee on Foreign Relations from 1985 to 1987 and from 2003 to 2007, serving as the ranking member of the committee from 2007 until his departure in 2013. Lugar also twice served as Chairman of the Senate Committee on Agriculture, Nutrition and Forestry, from 1995 to 2001 and briefly again in part of 2001. Much of Lugar's work in the Senate was toward the dismantling of nuclear, biological, and chemical weapons around the world, co-sponsoring his most notable piece of legislation with Georgia Democrat Sam Nunn: the Nunn–Lugar Act.

Following his service in the Senate, Lugar created a nonprofit organization which specializes in the policy areas he pursued while in office.

Early life, education, and early career[edit]

Richard Lugar was born on April 4, 1932, in Indianapolis, Indiana, the son of Bertha (née Green) and Marvin Lugar.[1] He was of part German descent.[2] Lugar attended Indianapolis Public Schools. During this time he attained the rank of Eagle Scout, the Boy Scouts' highest.[3] Later, he became a recipient of the Distinguished Eagle Scout Award from the Boy Scouts of America.[4] He graduated first in his class at Shortridge High School in 1950 and from Denison University in 1954, where he was a member of Beta Theta Pi.[5] He went on to attend Pembroke College, Oxford, England, as a Rhodes Scholar and received a second bachelor's degree and a master's degree in 1956.[6] He served in the United States Navy from 1956 to 1960; one of his assignments was as an intelligence briefer for Admiral Arleigh Burke. He achieved the rank of Lieutenant, Junior Grade.[7]

Lugar managed his family's 604-acre (244 ha) Marion County corn, soybean and tree farm. Before entering public life, he helped his brother Tom manage the family's food machinery manufacturing business in Indianapolis.[5]

Indianapolis politics and mayorship[edit]

Lugar served on the Indianapolis Board of School Commissioners from 1964 to 1967. He was elected mayor of Indianapolis in 1967, at the age of 35, defeating incumbent Democrat John J. Barton, and began serving the first of two mayoral terms in 1968. (A political cartoon of the time questioned how an Eagle Scout could survive in the world of politics.)[3] He was closely associated with the adoption of Unigov in 1970, which unified the governments of Indianapolis and Marion County. The Unigov plan helped trigger Indianapolis's economic growth and earned Lugar the post of president of the National League of Cities in 1971. In 1972, Lugar was the keynote speaker at the Republican National Convention.[8] During this time he became known as "Richard Nixon's favorite mayor", owing to his support for devolving federal powers to local communities.[9] When Nixon visited Indianapolis in February 1970, he stated during a speech that he would meet with Lugar and other mayors ahead of a conference with Governors on environmental issues.[10] On March 14, 1974, Lugar dismissed Police Chief Winston L. Churchill following allegations of widespread corruption in the Indianapolis Police Department. Lugar stated the dismissal came following meetings with dozens of policemen and after having had the counsel of a seven member committee of citizens to aid in the investigation.[11]

U.S. Senate[edit]

Elections[edit]

See also: Electoral history of Richard Lugar

Lugar in 1977, during his first term in the Senate

Lugar first ran for the U.S. Senate in the 1974 election and lost to incumbent Democratic U.S. Senator Birch Bayh (51–46%).[12] Two years later, he ran against Indiana's other U.S. senator, Democratic Senator Vance Hartke, defeating him in a massive landslide, 59%–40%.[13]

In 1982, he defeated Democratic U.S. Congressman Floyd Fithian (54–46%) to win a second term,[14] and six years later Lugar won reelection to a third term, defeating Democrat Jack Wickes (68–32%).[15] In 1994, Lugar won a fourth term, defeating Democratic former U.S. Congressman Jim Jontz (67–31%).[16] He became the first U.S. senator from Indiana elected to a fourth term.

Lugar went on to serve a total of six terms in the Senate, defeating Democrat David Johnson (67–32%) in 2000[17] and defeating Libertarian Steve Osborn (87–13%) in 2006[18] in a contest in which the Democratic Party did not field a candidate. His was the highest-percentage win of the 2006 Senate elections despite a Democratic takeover of Washington.

In 2012, Lugar ran for reelection to a seventh term. Due to Lugar's unpopularity among some Tea Party voters because of his positions regarding illegal immigration, voting to confirm then-U.S. Supreme Court nominees Sonia Sotomayor and Elena Kagan, the DREAM Act, the New START Treaty, some gun control bills, and congressional earmarks, he was challenged by Tea Party-backed State Treasurer Richard Mourdock in a Republican primary.[19][20] Mourdock defeated Lugar, 61–39%, and went on to lose the general election to Democratic Rep. Joe Donnelly. Lugar carried only two counties, Boone and Marion.[21][22] He was the first six-term U.S. senator to lose his seat in a primary election since Kenneth McKellar in 1952.

Richard Lugar with then-Senator Barack Obama in August 2005 near Perm, Russia

Tenure[edit]

1970s[edit]

Future Governor of Indiana Mitch Daniels served as Lugar's chief of staff from 1977 to 1982.[23] During the 1980 Republican National Convention, Lugar was rumored as a potential Vice Presidential nominee for Presidential nominee Ronald Reagan.[24]

In his first months, Lugar backed legislation prompting the Senate to adopt a stringent code of ethics intended to assist with the restoration of public confidence in Congress.[25]

On June 30, 1978, the Senate voted to approve granting New York City long term federal loan guarantees of $1.5 billion that the city had cited as essential to its prevention of bankruptcy. The measure was a compromise proposal by Lugar and Wisconsin Senator William Proxmire. Later that day, during a news conference, Senator Jacob K. Javits thanked Lugar and Proxmire.[26]

1980s[edit]

Lugar attended the January 7, 1980 signing ceremony of the Chrysler Corporation Loan Guarantee Act of 1979 in the Cabinet Room. Lugar addressed President Jimmy Carter during the ceremony by thanking him for signing what Lugar called "very humane and compassionate legislation" that was important for the United States.[27]

In the early months of the Reagan administration, Lugar supported its program to eliminate all restrictions on planting and marketing of peanuts. An April 30, 1981 vote by members of the Senate Agriculture Committee continued the restrictions.[28]

On May 11, 1981, the Senate Foreign Relations Committee voted in favor of implementing restrictions on American aid to El Salvador requiring President Reagan to verify the Salvadorian government was using the funds to implement human rights along with political and economic changes. The measure was opposed by Lugar who voted against the entirety of its conditions.[29]

Lugar was one of four senators on the Senate Foreign Relations Committee to vote against the Senate rejecting the nomination of Ernest W. Lefever for Assistant Secretary of State for Human Rights on June 5, 1981.[30]

On October 15, 1981, Lugar voted against the recommendation of the disapproval toward the Reagan administration's intent to sell Awacs radar surveillance planes and other air-combat equipment to Saudi Arabia.[31]

On December 2, 1981, Lugar voted in favor[32] of an amendment to President Reagan's MX missiles proposal that would divert the silo system by $334 million as well as earmark further research for other methods that would allow giant missiles to be based. The vote was seen as a rebuff of the Reagan administration.[33][34]

In 1982, Lugar cosponsored a housing bill that would provide middle-class purchasers of new homes with mortgage subsidies, which he referred to as "an emergency jobs program" that would provide 700,000 Americans with jobs in the housing and related industries while costing $5 billion over the following five years. The cancellation of an April meeting of the Senate Banking, Housing, and Urban Affairs Committee to discuss how far-reaching the bill should be was seen as crippling to its chances of implementation.[35]

On December 23, 1982, Lugar voted in favor[36] of a 5 cent a gallon increase on gasoline taxes across the U.S. imposed to aid the financing of highway repairs and mass transit. The bill passed on the last day of the 97th United States Congress.[37][38]

On July 13, 1983, Lugar voted in favor[39] of an authorization to appropriate $130 million toward the development of nerve gas bombs and shells.[40][41]

Lugar led the February 2, 1984 hearing of William A. Wilson, the nominee of President Reagan for United States Ambassador to the Holy See.[42]

In March 1984, Lugar voted in favor of a constitutional amendment authorizing periods in public school for silent prayer,[43] and President Reagan's unsuccessful proposal for a constitutional amendment permitting organized school prayer in public schools.[44][45]

Lugar voted against the May 1984 budget freeze meant to reduce the budget deficit.[46][47]

United States Secretary of Transportation Elizabeth Dole announced President Reagan's support for legislation that would force states to raise the minimum drinking age to 21 during a news conference on June 13, 1984. Lugar was in attended the news conference and stated that Dole and himself had convinced President Reagan to change his mind through "the work of groups like MADD (Mothers Against Drunk Driving) and the concern of hundreds of high school organizations called SADD (Students Against Driving Drunk)". Lugar noted his commitment to working on bipartisan support for the legislation.[48] The same month, Lugar voted in favor of legislation restricting federal highway funds for states that did not raise the minimum age for drinking to 21.[49][50]

On May 9, 1986, Lugar held a news conference designed to coincide with the beginning of the Manila visit by Secretary of State George P. Shultz, during which he criticized the Reagan administration for what he perceived as a lack of support for the Philippine government under the rule of President of the Philippines Corazon Aquino and accused former Philippines President Ferdinand E. Marcos of using his Hawaii haven as an area to make hundreds of telephone calls to former allies still in Manila for the purpose of making his potential return to power of active speculation.[51] The fiscal year of 1986 included the United States providing 236 million to the Philippines. President Reagan also sought an additional 100 million for economic aid and 50 million for military aid. During a June 3 panel on the subject of providing aid for Manila, Lugar stated his support for the United States providing another 100 million to the government of President Aquino and called on the chamber to recognize Aquino's government "is threatened not only by a Communist insurgency but also by a possible challenge from the political right".[52]

In November 1986, amid the Iran–Contra affair, Lugar stated that President Reagan did not understand the law requiring a president to inform Congress in a timely fashion over operations and that Reagan's rhetoric on the third party arm shipments had been confusing. He also stressed that the president had not been damaged in his credibility.[53] Around this time, Lugar conferred with John Poindexter, a key figure in the scandal.[54] After the 1987 State of the Union Address, Lugar stated that he believed President Reagan had taken responsibility for the Iran–Contra affair by acknowledging that the deal had been unsuccessful.[55]

The 1986 midterm election featured 22 of the 53 Senate Republicans up for reelection. In late 1984, Lugar predicted that "a number of our people are not going to win in '86" unless there was economic growth.[56] The Republicans lost eight seats that election cycle. Shortly after the midterms, on November 13, it was disclosed that Senator Jesse Helms would challenge Lugar for ranking Republican on the Senate Foreign Relations Committee, Helms telling Lugar in a letter that the challenge would not have occurred had the Republicans maintained a majority in the Senate as "the ranking minority post is a different matter".[57][58] On January 6, 1987, Republican members of the Senate Foreign Relations Committee voted unanimously to retain Lugar as their ranking member. After the results, Lugar stated that he saw his win as a vote of confidence in his leadership.[59]

In January 1988, the Senate began work on the ratification of the Intermediate-Range Nuclear Forces Treaty.[60] Later that month, Lugar met with German Minister for Foreign Affairs Hans-Dietrich Genscher to discuss the INF Treaty, Lugar stating afterward that he was confident the treaty would eventually be ratified despite developments in the process.[61] Lugar believed technical errors existed within the treaty, aligning him with Senate critics of the measure, but differed from them on when they should be improved.[62] Lugar voted in favor of the treaty in May when it passed overwhelmingly in the Senate on May 27.[63][64]

Lugar attended the July 11, 1988, White House meeting on the subject of legislation to provide financial relief to farmers affected by the showers in the Midwestern and Southern United States, Lugar during which he indicated that there was willingness on the part of his political party to support the measure.[65] On August 11, 1988, President Reagan signed the Disaster Assistance Act of 1988 into law. During the ceremony, President Reagan noted Lugar as one

of the members of Congress "who've done so much to make this possible".[66]

After Vice President George H. W. Bush selected Lugar's fellow Indiana senator Dan Quayle for his running mate in the 1988 Presidential election, Lugar spoke with Bush by telephone, and the presidential candidate explained his pick of Quayle: "The Vice President told me he wanted somebody of a distinctly different generation. It was obvious he felt that was more important than some other considerations. I certainly understand that."[67] In a September 28, 1988 news conference, Democratic vice-presidential nominee Lloyd Bentsen cited Lugar as one of three "heavyweight" Republican senators who were more qualified for the vice presidential nomination than Quayle.[68] On December 12, 1988, Lugar attended Vice President-elect Quayle's first news conference following the election, during which Quayle stated the Bush administration would be seeking his aid along with that of Dan Coats in pushing their agenda through Congress.[69]

1990s[edit]

In February 1990, Lugar announced that the congressional group President Bush named to observe Nicaragua elections the following month was disbanded following their being denied visas by the Nicaraguan government.[70]

In 1990, after President Bush nominated James E. Cason to be Assistant Secretary for Natural Resources and Environment, the latter received scrutiny for his record during the Reagan administration.[71] During a September hearing, Lugar "asked a series of probing questions on the spotted owl",[72] and questioned him during a hearing the following month regarding his record at the Interior Department. On October 19, 1990, the Senate Agriculture Committee voted to recommend Cason for Assistant Agriculture Secretary.[73][74]

on August 21, 1990, Lugar told reporters that the move to a marketing economy on the part of Vietnam had created the possibility for American investment provided that differences between Washington and Hanoi be resolved.[75]

On October 2, 1990, Lugar voted in favor of the nomination of David Souter for Associate Justice on the United States Supreme Court.[76][77]

In November 1990, amid President Bush's handling of the Persian Gulf crisis, Lugar observed that President Bush should "call back the Congress and get an affirmative vote to authorize our staying power over there so that the world knows that we're going to back up whatever the President is doing."[78]

In June 1991, Lugar joined fellow Senators William Cohen and John Warner in revealing their dissent with space-based weapons, a central component of the Bush administration's version of the Strategic Defense Initiative, in a letter and speeches. The three offered an alternative that "would defer the deployment of 1,000 missile-destroying rockets in space, while calling for greater levels of ground-based missile defenses".[79]

On November 25, 1991, the Senate voted in favor of approving the Bush administration-backed package to transfer $500 million of the Pentagon budget to assist with dismantling Soviet nuclear weapons.[80] In support of the measure, Lugar said, "We can either seize the opportunity for cooperative efforts in this field now or witness a quantum leap in the proliferation of weapons of mass destruction in the next few years."[81]

During the 1992 election cycle, Lugar stated President Bush needed to signal that his reelection campaign was "a new campaign with a new game plan and a new vigor" and the best results would be formed through a message on "growth and jobs".[82]

In February 1993, after Secretary of State Warren Christopher declared that the United States would only use military power in seeking a settlement as it pertained to Bosnia, Lugar's spokesman stated that during a telephone conversation between Christopher and Lugar, the secretary of state said "that the United States could contribute as many as 5,000 to 10,000 American troops to a 40,000-member NATO force that would go to Bosnia under United Nations auspices after a new peace accord is concluded".[83] Lugar attended the April 28, 1993 meeting between President Clinton and lawmakers over American involvement in Bosnia. Following its conclusion, Lugar stated the president's views: "He had a positive feeling towards lifting the embargo—that justice has to be served in that respect. But the President was much less certain about heading down the trail of air strikes."[84] Weeks later, on May 11, Lugar met with President Clinton on the subject of Bosnia, Lugar stating afterward that President Clinton had developed "a plan that he has been pushing steadily" and was in favor of containing the Bosnia disaster.[85] Lugar was of the view that the United States wanted a full partnership with Europeans that could only arise from "recognition on their side that our men and women in the armed forces are taking risks right now".[86]

On November 20, 1993, Lugar voted in favor of the North American Free Trade Agreement.[87] The trade agreement linked the United States, Canada, and Mexico into a single free trade zone, and was signed into law on December 8 by President Clinton.[88]

In December 1994, President Clinton announced the nomination of Dan Glickman for Secretary of Agriculture.[89] During the ceremony, Glickman stated that agriculture should not be immune to change and cited Lugar as an official "asking good questions about the next farm bill".[90] During a March 1995 Senate hearing, Lugar indicated his distaste with Glickman not supporting the latest accord under the General Agreement on Tariffs and Trade the previous November. Lugar afterward spoke positively of Glickman.[91]

On August 3, 1997, Lugar stated his support for convening a hearing for William Weld for United States Ambassador to Mexico and overlook Senator Jesse Helms, noting that a Senate chairman "cannot be dictatorial, ultimately, when a majority of the committee, a majority of the Senate, a majority of the American people, want action".[92]

On February 12, 1999, Lugar voted in favor of both articles of impeachment against President Clinton,[93] calling his relationship with White House intern Monica Lewinsky "shameless, reckless and indefensible",[94] and criticizing him for creating a negative environment.

"Simply to be near him in the White House has meant not only tragic heartache for his wife and his daughter but enormous legal bills for staff members and friends who admired him and yearned for his success but who have been caught up in his incessant 'war room' strategies to maintain him in office."[95]

In October 1999, Lugar voted against the Comprehensive Nuclear-Test-Ban Treaty. The treaty was designed to ban underground nuclear testing and was the first major international security pact to be defeated in the Senate since the Treaty of Versailles.[96][97]

2000–2008[edit]

During the August recess of 2005, Lugar and then-freshman Senator Barack Obama of neighboring Illinois visited Russia, Azerbaijan, and Ukraine to inspect nuclear facilities there.[98] He was detained for three hours at an airport in the city of Perm, near the Ural Mountains, where they were scheduled to depart for a meeting with the President and the Speaker of the House of Ukraine. He was released after a brief dialogue between U.S. and Russian officials and the Russians later apologized for the incident. In January 2007, President Bush signed into law the Lugar–Obama Proliferation and Threat Reduction Initiative, which furthered Lugar's work with Senator Sam Nunn in deactivating weapons in the former Soviet Union. The Lugar–Obama program focuses on terrorists and their use of multiple types of weapons.[99] In April 2006, *Time* magazine selected Lugar as one of America's 10 Best Senators.[100]

Senator Lugar tours an agricultural research facility.

Although Lugar's party was then in the minority in the Senate, he had good relationships with President Obama and Vice President Joe Biden. Lugar was named an honorary co-chairman of their inauguration.[101] On the day of the final 2008 presidential debate, Lugar gave a speech at the National Defense University praising Obama's foreign policy approach and warning against the isolationist, reactive policies espoused by John McCain.[102] At that debate, Obama also listed Lugar as among the individuals "who have shaped my ideas and who will be surrounding me in the White House".[103] There were rumors that either Obama or McCain would select Lugar to be Secretary of State, but that he preferred to keep his Senate seat.[99][104]

Obama administration[edit]

On January 13, 2009, Lugar participated in the confirmation hearing for Secretary of State nominee Hillary Clinton, raising questions on the potential conflict of interest between her husband Bill's charitable activities and her new position.[105] Lugar offered praise to Clinton as "the epitome of a big leaguer",[106] Lugar's spokesman Andy Fisher said that before the hearing, Lugar offered Clinton's staff four ways in which to increase the transparency of former President Clinton's fundraising.[107]

On March 18, 2009, Lugar cast his 12,000th Senate vote, putting him in 13th place for most votes. During his 32 years as a Senator, he had a 98% attendance record.[108]

Committee assignments[edit]

- **Committee on Agriculture, Nutrition, and Forestry**
- **Committee on Foreign Relations**
